# Identification of Gum Arabic (Acacia Seyal) Constituents Using Laser Induced Breakdown Spectroscopy 

Nafie A. Almuslet* Mubarak M. Ahmed and Mashair A. Mohammed<br>Department of laser systems, Institute of laser - Sudan University of Science and Technology

#### Abstract

The aim of this work is to identify the Constituents of Gum Arabic type Acacia seyal.var.seyal. using laser induced breakdown spectroscopy (LIBS). Five Samples of the gum were collected from different locations within the gum belt of Sudan. The samples were irradiated with pulse Nd-YAG laser of pulse energy equal 80 mj , The resultant emission spectra were recorded and each spectral line in the spectra were identified .It was found that the sample contain the elements $C, O, H, N, B r, A r, S, P$, and the major cation $M g, C a, K, N a$, in addition to trace heavy metals $\mathrm{Fe}, \mathrm{Cr}, \mathrm{Th}$ and Ti .

Keywords: LIBS; emission spectroscopy; laser in Gum Arabic (Acacia Seyal)

## I. Introduction

Laser-induced breakdown spectroscopy (LIBS) is a type of atomic emission spectroscopy which uses a highly energetic laser pulse as the excitation source [1, 2]. LIBS operate by focusing the laser onto a small area at the surface of the specimen; when the laser is discharged it ablates a very small amount of material, in the range of nanograms to picograms, which generates a plasma plume. At the high temperatures during the early plasma, the ablated material dissociates (breaks down) into excited ionic and atomic species. During this time, the plasma emits a continuum of radiation which does not contain any useful information about the species present, but within a very small timeframe the plasma expands at supersonic velocities and cools. At this point the characteristic atomic emission lines of the elemental constituent of the sample can be observed. The delay between the emission of continuum radiation and characteristic radiation is in the order of $10 \mu \mathrm{~s}$. This is why it is necessary to temporally gate the detector [3, 4]. LIBS can be used to investigate different materials especially those composed of large molecules such as Gum Arabic. Acacia seyal and acacia Senegal are two types of trees from which Gum Arabic is extracted and used as food additive. Both types of trees grow in a narrow belt of latitudes, known as the gum belt, and stretches across northern Africa to the bottom edge of Chad, including Sudan, Eritrea, Kenya, Mali, Mauritania, Niger, Nigeria and Senegal [5]. Most of the top-grade gum used in the beverage industry today comes from Sudan and Chad. Other countries, such as Uganda and Eritrea, are periodically developing acacia crops. Of the two, Acacia Senegal yields the stronger and more-expensive emulsifier. Usually the Acacia Senegal and Acacia seyal tree exude gum when they are subjected to injury of scratch of their brake intentionally or accidently. It is customary to tap these trees and allow for the gum to exude as a viscous fluid,that harden when exposed to air and became in a form of nodules that are collected later. [6.7].This work aimed to use LIBS for Identification of Gum Arabic (Acacia Seyal).

## II. The Experimental part

### 2.1 Experimental Setup:

Figure (1) illustrates the LIBS setup which was used in this work. The LIBS system composed of Qswitched Nd- YAG Laser (Laser wavelength is 1064 nm , pulse duration 10ns, Pulse Energy 80 mj , Spot size 28 mm , and repetition rate 2 Hz ), Ocean Optics 4000+ spectrometer, connected with PC.

Figure (1): Schematic diagram of the setup

### 2.2 The Materials

Five samples of Acacia Seyal (Talha) obtained from different locations in Sudan. were used in this work, they are illustrated in table (1)

Table (1) Samples Grouping

| Classification | Location of samples collection |
| :--- | :--- |
| Sample (1) | South Kordofan state |
| Sample (2) | North Kordofan state |
| Sample (3) | Blue Nile state |
| Sample (4) | White Nile state |
| Sample (5) | Gadaref Area, eastern of Sudan |

### 2.3 Experimental Procedure:

Each sample was put in a quartz cell and irradiated by the Nd-YAG laser where the spark of the sample plasma was collected by a fiber optic to the spectrometer which was interfaces to a computer. The emission spectra were collected in the range from 200-900 nm. In order to test the homogeneity of Gum Arabic samples, several LIBS measurements were performed at its surface. The recorded spectra of the samples were analyzed using NIST data.

## III. Results and discussion

Figures (2) to (6) show the LIBS emission spectra for the samples of Acacia Seyal (Talha), after irradiation with 80 mJ pulse energy. Atomic spectra database and Hand book of Basic Atomic Spectroscopic Data were used for the analysis of the emission spectra .Each spectral line was assigned to the corresponding constituent element or ion in the sample, Table (2) lists the wavelength and intensities of the different spectral lines in the emission spectra for the samples studies along with the constituent elements corresponding to each line.

Figure (2): LIBS emission spectrum of sample (1)

Figure (3): LIBS emission spectrum of sample (2)

Figure (4): LIBS emission spectrum of sample (3)

Figure (5): LIBS emission spectrum of sample (4)

Figure (6): LIBS emission spectrum of sample (5)
Table (2): The analyzed data of the samples after irradiation by laser energy of 80 mJ

| Element | $\lambda(\mathrm{nm})$ | Intensity of emission (a.u) |  |  |  |  |

The elements constituting the samples observed in the emission spectra were $\mathrm{C}, \mathrm{H}, \mathrm{N}, \mathrm{O}, \mathrm{S}, \mathrm{P}, \mathrm{Fe}, \mathrm{Na}, \mathrm{Ca}, \mathrm{Mg}, \mathrm{K}$, $\mathrm{Cr}, \mathrm{Br}, \mathrm{Ti}, \mathrm{Ar}$, and Th . These elements reflects the established composition of Gum Talha reported in scientific literature [8]. Gum Talha is a natural polysaccharide builds mainly from galactose, arabinose, rhaminose and glucuronic acid, with small proportion of proteineceous material [9]. Hence it is expected to observe elements like $\mathrm{C}, \mathrm{H}, \mathrm{O}$, as main constituent of carbohydrates. Also the presence of the elements like; N, S and P is expected as Gum Talha contains proteineceous material. The elements $\mathrm{Mg}, \mathrm{Ca}, \mathrm{K}$ and Na were observed by LIBS analysis in all samples collected from the different locations. This observation is in agreement with previous studies, [10.11]. Also the elemental analysis of gum Talha by LIBS provide a supportive evidence for the presence of heavy metals like Fe and Cr which had been reported by other researches.[12]. It is interesting to report, for the first time, the presence of $\mathrm{Br}, \mathrm{Ar}, \mathrm{Ti}$ and Th in Gum Talha. These elements have not been observed by techniques usually used for elemental analysis of gum, such as Atomic Absorption spectroscopy (AAS) and inductively coupled plasma spectroscopy (ICP). It is also of interest to note the presence of higher ionization states of some of the elements present in the gum samples subjected to study such as: $\mathrm{Fe}^{+3}, \mathrm{Fe}^{+2}, \mathrm{Cr}^{+3}, \mathrm{Th}^{+2}, \mathrm{Ca}^{+2}, \mathrm{Cr}^{+5}, \mathrm{Ti}^{+2}$ and $\mathrm{Ti}^{+3}$. $\mathrm{The}^{2}$ results obtained in this work demonstrated that LIBS is a suitable technique for elemental analysis of gum Arabic and it is also a sensitive analytical method capable of detecting elemental species that could not be observed in other techniques.Although the study had demonstrated that Gum Talha consist of uniform elemental composition, the influence of location of sample collection was well presented and evident from the differences in the emission intensities of the same elements in the samples.

## IV. Conclusions

Elemental analysis of gum Talha can be done conveniently and with great accuracy by LIBS technique. Gum Talha was found to contain elements like $\mathrm{Ar}, \mathrm{Ti}, \mathrm{Br}$, and Th , which had been reported here for the first time.
