Abstract: This study was carried out to investigate the proximate and phytochemical constituents of young leaves of Myrianthus arboreus and Spargonophorus sporgonophora. The result of the proximate analysis revealed that M. arboreus leaves contained moisture content of 40.10±0.14%, crude fat of 6.45±0.18%, ash of 3.30 ± 0.16, protein of 3.56±0.10%, Crude fibre of 3.74±0.14%, dry matter of 70.30 ± 0.57% and carbohydrate of 12.58 ± 0.10% while S. sporgonophora leaves contain moisture content (3.20 ± 0.84%), Crude Fat (6.01± 0.01%), ash (3.52±0.18%), Protein (4.20 ± 0.00%), Crude fibre (3.74±0.01%) and dry matter (8.10±0.14%). Results of the mineral analysis showed that their leaves contained high concentrations of Calcium, Sodium, Iron and Potassium. Phytochemical screening showed the presence of alkaloids, flavonoids, Tannins and Glycosides. Concentrations of flavonoids and alkaloids were high in the two species. Saponins were absent in M. arboreus while phenols was not found in S. sporgonophora. The results of this study indicated that these local vegetables contained mineral elements and secondary metabolites that are good sources of nutrients for human diet and therapeutic uses.

Key words: Phytochemical constituents, therapeutic, proximate analysis, Myrianthus arboreus, Sparganophorus sparganophora.

I. Introduction

Green leafy vegetables play a vital role in the food culture of people in Nigeria and Africa as a whole (1). They are the cheapest and most valuable sources of nutrients such as minerals salts, vitamins, essential fatty acids and fibre which are usually found in daily diets (2). They have the cheapest and most abundant sources of protein (3). A previous study by (4) reported that vegetables are not only cheap sources of nutrients but are also the common sources.

Recently, in Nigeria, there has been an increase interest and awareness in consumption of wild vegetables such as Solanum nigrum, Colocassia esculenta, Bidens pinnata, Cerathoteca sesamoides, Gongronema latifolium, Cnidococlus chayamansa and Scenecio biafrae. Most of these traditional vegetables are eaten in the rural areas or in the communities where they are being planted or commonly found. These vegetables are underutilized when compared to the common varieties due to the fact that little knowledge was known and documented about the nutritional and medicinal importance of these vegetables (per. Comm.). Myrianthus arboreus belongs to the family Moraceae. It is a monoeic forest re-growth tree up to 15m high with a characteristic false fruit which is yellow when ripe. Leaves are very large, alternately shaped, digitately 5-7 foliolate. Young leaves are usually red in colour. Male inflorescences are yellow, branched and produced panicle like axillary pairs towards later part of the dry season. The female inflorescences are paired, stalked, greenish clusters (pendunculate). Fruit is syncarpous and basally fused, yellow drupes up to 10cm with stylar remains projecting from each drupe. The leaves are used in preparation to treat dysentery, diarrhea and vomiting. In eastern Nigeria plaster made of beaten leaf are applied to boil (5). Chopped leaves are eaten raw with salt for heart problems and pregnancy complications. Sap from the leaves is applied tropically for toothache, to the chest for bronchitis or for sore throat (6). Sparganophorus sparganophora belongs to the family Asteraceae. It is a culinary herb in most African countries. The leaves are boiled in water, drained completely and added to soup or consumed as a vegetable. It is also widely used medicinally in a number of countries. Information is however scanty on the nutritional and phytochemical compositions of these uncommonly consumed vegetables. Hence there is need to evaluate the nutritional and phytochemical compositions of these uncommonly consumed vegetables.

II. Materials and Method

The young shoots of the two indigenous vegetables (M. arboreus and S. sparganophora) were collected from a farmland in Iyin-Ekiti, Ekiti State, Nigeria in the month of February, 2014. The leaves were separated from the stalk, washed through in distilled water and air dried in the laboratory for three weeks. They were later milled into powders using electric blender. The powdered samples obtained were stored in plastic bottles at ambient temperature until when needed for use.
Chemical analysis

The proximate analysis were carried out in duplicates and the data presented were the average value. The estimation of moisture, ash, crude fat and crude fibre were determined in accordanc

Mineral Analysis

Elemental analyses were carried out using an atomic absorption spectrophotometer and a flame photometer to determine Calcium, Sodium, Potassium and Magnesium contents. The data obtained in parts per million (p.p.m) was converted to mg/g. Aluminum, Iron and Phosphorus were determined calorimetrically.

Phytochemical Screening

This analysis determines qualitative and quantitative composition of secondary metabolites such as flavonoids, alkanoids, saponins, phenols and glycosides in the plant species.

III. Results and Discussion

The results of the proximate, mineral and phytochemical compositions of the leafy vegetables used in this study are as shown in Tables 1, 2, 3 and 4. The protein content of the leaves of M. arboreus and S. sporgonophora was 4.20% and 3.56% respectively. These values were lower than that reported by (10) for some other leafy vegetables commonly consumed in Nigeria like Brassica oleracea (11.67%) and Launnea taraxacifolia (17.64%). However, results can compare favourably with values in other traditionally consumed vegetables such as Cnidoscolus aconitifolina (2.96%), Solanum nigrum (3.10%), Crassocephalum crepidioides (1.76%) and Colocassia esculenta (2.67%) (11). Also, the result obtained for protein content is similar to the report of (12) who gave the crude protein values for Solanum nodiflora, Senecio biafrae and Cnidoscolus...
Phytochemical and Proximate Evaluation of Myrianthus Arboreus (P. Beau.) And Sparganophorus

The crude fibre content values obtained were higher than the values reported for Manihot esculenta (3.73%), Colocassia esculenta (3.30%), Cnidoscolus chayamansa as 3.03%, 3.03% and 5.91% respectively. Crude fibre content of the leaves was within the range of (1.22%-15.90%) reported for some selected Nigerian leafy vegetables (21). The values obtained in this study fell below carbohydrate values for Momordica balsamina (39.05%). The carbohydrate content of the leaves of M. arboreus (7.20%) and S. sparganophora (12.58%) were considerably low compare to some leafy vegetables like Tribulus terrestris “Tsada” and Corchorus tridens (22). Ash content of the two leafy vegetables was lower than that reported for Diplazium summaitii (Nyama idim) (23) and those of Tridax procumbens (24). The knowledge of ash content gives an indication of the mineral composition of the leaves. The two vegetables investigated had higher moisture content of 35.20% and 40.10% respectively. The moisture content was lower than those reported for some other vegetables grown in South west, Nigeria like: Lannea taraxacifolia (79.77%), Ocimum gratissimum (83.87%), Vernonia amygdalina (78.60%) and Bident pinnata (85.53%) (11). However, the values were comparatively higher than those values reported for vegetables like Moringa oleifera (5.9%) (25) and Hippocrotea myriantha (6.93%). The moisture content of food is used as a measure of stability and susceptibility to microbial contamination (26). The high moisture content found in the leaves of plants in this study agreed with the report that water is the most abundant component in all vegetables (27). The results of mineral analysis of the vegetable leaves (Table 2) indicated that the minerals detected were calcium, potassium, magnesium, sodium and iron. The leaves of S. sparganophora and M. arboreus showed high level of calcium for sustaining strong bones, muscular contraction and relaxation, blood clothing and absorption of vitamins B12 (1,28). These values could be said to be low since the values can only contribute about 6.83% and 7.51% respectively to the Recommended Daily Allowance (RDA) values of Calcium for an adult man with 300kcal/day whose recommended energy intake is 120mg (29,30,31). The Potassium content were higher than the values found in Cnidoscolus chayamansa (4.02%), Solanum nodiflorum (0.19%) and Solanum biafrae (0.18%) (12) and also values reported for Amaranthus hybridus leaves (32). The leaves of S. sparganophora can contribute about 4.00% to RDA of the Recommended Daily Allowance (RDA) of Potassium which is 200mg for adults (29). The value obtained for Sodium is lower compare with the previous values reported for some selected Nigerian vegetable leaves (21). Sodium and Potassium are important intracellular and extracellular cations respectively. The importance of NA/K ratio in the body in controlling high blood pressure cannot be over emphasized (33). The result of Iron content of M. arboreus was 7.44mg/100g which was lower than the value found in Ocimum viridis and Ocimum gratissimum (34). Iron content of S. sparganophora was 10.58g/100mg which is high when compared with the value obtained for Tribulus terrestris “Tsada” and in some cultivated vegetables such as spinach, lettuce and cabbage but compared favourably with values found in Mucuna roggei (10.58mg/100g) (20) and Ocimum gratissimum (10.32mg/100g) (34). Green vegetables are recommended for anemic convalescence. The value for iron in the leaves though lower when compared with RDA (mg/day) could help in boosting the blood level in anemic conditions (29). The Magnesium content of the leaves was 2.68mg/100g and 3.90mg/100g respectively which are higher than the values reported for C. chayamansa, S. nodiflorum and S. biafrae but lower than that reported for bitter leaf (V. amygdalina) (61.08mg/100g), Basella alba (92.51mg/100g), Hibiscus sabdariffa (120mg/100g) (21). The magnesium content in the samples investigated was lower when compared with RDA for magnesium in adult which is 350mg/day (29).

The phytochemical screening of the leaves of M. arboreus and S. sparganophora (Table 3) showed that the leaves of the two samples contained flavonoids, alkaloids, tannins and cardiac glycoside. The presence of these phytochemical could have been responsible for their medicinal values as well as physiological activities (34). High concentration of flavonoids and alkaloids were recorded in both samples while concentrations of saponins and tannins are moderate in the leaves of plants investigated (Table 4). Flavonoids are widely distributed in plants fulfilling various functions. They have been reported to have antibacterial, anti-inflammatory, antiallelic, antimutagenic, antiviral, antithrombotic and vasodilatory activity (35). Alkano...
nitrogen-containing compound are commonly found to have antibacterial properties due to their ability to intercalate with DNA of the microorganisms (37). (38) reported that alkanoids are powerful pain relievers, have an antipyrexic action, a stimulating effect and can act as tropical anesthetic in ophthalmology. Saponins were found in S. sporgonophora but absent in M. arboreus leaves. Presence of saponins had been reported to possess both beneficial and deleterious properties. (39,40). The presence of Tannins in the leaves also agreed with the previous works of (11),(41) and (34) who also discovered traces of tannins in some leafy vegetables grown and consumed in Nigeria. Tannins are known to have antiviral, antibacterial and anti-tumor properties. Tannins can also be effective in curbing hemorrhages as well as restrict bare swellings. When applied internally, tannins affect the walls of the stomach and contract or squeeze the membranes in such a manner that secretions from the cells are restricted. Long term and / or excessive use of herbs / vegetables with high concentration of tannins are not advisable (42). Hence, vegetables with moderate concentration of tannins is good for human health (1,28). Phenols were present in M. arboreus and absent in S. sporgonophora leaves. Phenols are strong antioxidants and play a role in the prevention and management of chronic diseases such as cancer and cardiovascular disease. (43) reported that plant phenols may interfere with all stages of the cancer process resulting to reduction of cancer risk.

IV. Conclusion

This study has provided useful biochemical information on nutrition and phytochemical compositions of M. arboreus and S. sporgonophora leaves. The results obtained revealed that M. arboreus and S. sporgonophora which are local and underutilized vegetables have appreciable amounts of nutrients such as calcium, potassium, iron, protein and anti-nutrients. This suggests that the indigenous leafy vegetables may serve as a constituent of human diet supplying the body with minerals, protein and energy for normal growth. The presence of phytochemical also contributes to their medicinal potentials.
