RSA Key Generation Using Combination of Fingerprints

Sharda Singh[1], Dr. J. A. Laxminarayana[2]
[1, 2](Department of Computer Engineering, Goa College of Engineering/ Goa University, India)

ABSTRACT: *The security of any encrypted data relies upon the cryptographic keys in use. The strong cryptographic key shall be lengthy, random and unique. A biometric feature such as fingerprint can provide the uniqueness factor, whereas randomness can be induced using different combinations of fingerprints. We propose a technique to generate the asymmetric key pair (for RSA) by making use of combination of fingerprints.*

Keywords – *Biometrics, Cryptography, Fingerprints, Key Generation, Minutiae.*

I. INTRODUCTION

In recent years, the progress in the communication technologies is resulting in huge transfer of the digital data in the publicly shared media. To secure these shared data, there is a significant interest shown by the researchers in the cryptographic domain leading to many innovative and efficient encryption methods. Every encryption method needs to use strong keys. The cryptographic keys shall be a large unpredictable random number. There are various methods to generate such keys; some methods are proposed to generate cryptographic keys from the biometric features such as iris, fingerprints, signature etc. as in [2, 3, 4, 6, 7, 8, 9, and 13]. There is a significant growth in the field of biometric technologies in past few years, and many of them are deployed according to the specific application and their acceptability to the users [3, 5, and 10]. One such type of method uses concept of asymmetric key cryptography: In asymmetric key cryptography two keys are required. They are known as public and private keys. The public key is given to everyone and the private key is kept secret [12]. The pair of keys is mathematically linked to each other in such a way that data encrypted with public key can only decrypted using private key and vice-versa. There are various asymmetric cryptographic algorithms like RSA [10] which have shown a very good performance with regard to time to encrypt and decrypt as well as the ability to withstand attacks. In asymmetric key generation algorithm an unpredictable large random number is required to generate the pair of keys.

In this paper, a novel technique is proposed to generate the RSA key pair using combination of fingerprints. The motivation for this proposed method comes from the fact that biometrics are a complete source of identification and being possessed by every individual, it would work as a good source of cryptographic keys, which can easily be long, random and unique.

II. LITERATURE SURVEY

Features like iris and fingerprint are used for authentication most of the times. In [9], efforts were made to extract the uniqueness of these biometric features and combine them to form a unique key. Further, it was attempted to generate a secure cryptographic key by incorporating multiple biometrics modalities of human being, so as to provide better security. The proposed approach [9] is composed of three modules namely, 1) Feature extraction, 2) Multimodal biometric template generation and 3) Cryptographic key generation. Firstly, the features like minutiae points and texture properties are extracted from the fingerprint and iris images respectively. Then, the extracted features are combined together at the feature level to obtain the multi-biometric template. Lastly, a 256-bit secure cryptographic key is generated from the multi-biometric template. Similarly, the fingerprint image has been used to generate keys as in [2, 8].

A combination of fingerprint and signature based key generation is explained in [7] which provided a framework for designing an asymmetric biometric cryptosystem through which a user can send and receive secure information only by using his biometric features. As there are so many biometric features, the information shown in Table 1[3], justifies the selection of fingerprint to generate keys.

The comparison in Table 1 is based on seven factors:

- Universality: How universal the identifier is? Is it possessed by everyone?
- Distinctiveness: Can it be used to distinguish people?
- Permanence: Is the identifier permanent? If not then for how long is it there with the individual?
- Collectability: Can the identifier be captured and collected? If yes, how well?
- Performance: What is the speed of obtaining the identifier? How accurately does it get used?

- Acceptability: Is it acceptable to be used? How willing are the people to use it?
- Circumvention: how foolproof is the identifier? It should be hard to imitate it.

Table 1: Comparison of Various Biometric Technologies [3]. (Medium, high and low are denoted by M,H and L respectively)

Biometric Identifier	**Universality**	**Distinctiveness**	**Permanence**	**Collectability**	**Performance**	**Acceptability**	**Circumvention**
Face	H	L	M	H	L	H	H
Fingerprint	M	H	H	M	H	M	M
Hand Geometry	M	M	M	H	M	M	M
Iris	H	H	H	M	H	L	L
Keystroke	L	L	L	M	L	M	M
Signature	L	L	L	H	L	H	H
Voice	M	L	L	M	L	H	H

The biometric fingerprint is selected due to its high score in Table 1. It is found that, researchers have attempted to generate cryptographic keys using only single fingerprint [6, 8], or a fusion of two or more biometric features [4, 7, 9].

Fuzzy Vault Scheme [1] and Modified Fuzzy Vault Scheme [11] are proposed to handle the situations in which acquired biometrics are noisy due to wear and tear, improper acquisition of signal and inconsistent presentation. In [15], a method is proposed to generate a secure key for MAC algorithm using fingerprint based cryptography system. The key is generated using fingerprint patterns, which is stable throughout person's lifetime. There is a chance that the conventionally generated password may be hacked by trial and error method. But it is not possible to break the biometrics based security system easily.

III. PRE-REQUISITES

The pre-defined techniques and information used for the proposed method is presented below:

1.1. Crossing Number [16]

Crossing number is defined as the half of the sum of differences between adjacent pixels in eight connected neighborhood. This technique makes use of skeleton image / thinned image of ridge flow pattern to classify the ridge type. It uses a 3x3 window, using which neighborhood of each ridge pixel is scanned as shown in Fig. 1. The crossing number is calculated as per equation 1:

$$CN=0.5\sum P_i-P_{i+1} \quad \text{for } i=1 \text{ to } 8 \text{ and } P9=P1 \qquad (1)$$

P4	P3	P2
P5	P	P1
P6	P7	P8

Fig.1. 3x3 Window for Scanning Neighborhood Pixels

The ridge pattern is classified based on the CN value for that pixel according to Table 2.

Table I : Ridge Pattern Associated to Crossing Number Value

CN	**Ridge Pattern**
0	Isolated Points
1	Ridge Ending
2	Ridge Continuation
3	Ridge Bifurcation
4	Crossing Point

1.2. Working of the Biometric Fingerprint

Fingerprint recognition technology extracts features from impressions made by ridges on the fingertips. To generate keys from fingerprint we first and foremost need to capture the fingerprint images. We use a fingerprint capturing device for this purpose. The device can be an USB device or a parallel device with variety of sensor types. In every human fingerprint there are certain patterns made due to ridges and valleys which are almost unique. The various patterns are ridge endings, ridge bifurcations, isolated points, deltas, pores, lakes, spurs and crossing points. In the proposed model we extract the features namely ridge bifurcation, ridge ending, crossing points and isolated points.

IV. PROPOSED MODEL

A novel approach is proposed to key generation, which uses a combination of fingerprints to generate the RSA key pair. Fig. 2 shows the flow of the proposed method.

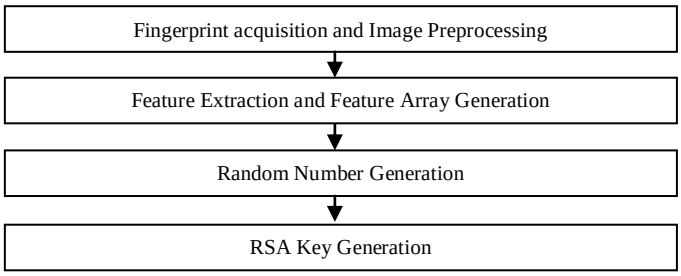

Fig.2. Flow of Proposed Model.

1.1. Image Acquisition and Preprocessing

Initially, all 10 fingerprints have been captured and among them select randomly 'n' of them, where 'n' (n<10) can be explicitly specified by the user. Initially the pre- processing and feature extraction techniques as in [13, 14] are applied to the captured images followed by the proposed algorithm to generate the key. The captured images are resized to 255x255px and the following image processing algorithms as described in [7, 8, 9, and 15] are applied.

- Histogram Equalization

It enhances the contrast of the fingerprint image at the places where the ridge lines are not very prominent (caused due to low pressure on the sensor). Here the basic idea is to map the gray levels based on the probability distribution of the input gray levels.

- Noise removal

This is achieved using filters like Median filter, Weiner or Gabor filter. It first estimates the noise in the image and removes the estimated noise to get the clearer image.

- Binarization

In this step the grey scale image is converted into binary image. This enhances the contrast between the ridge and the valleys in a fingerprint image. The image is binarized by considering the mean of all the neighbouring pixels around each pixel and giving a value 1 to that pixel if its intensity is greater than the mean value and 0 otherwise.

- Thinning

Application of morphological thinning operation to get the final image with a width of single pixel. The resultant image is the skeleton structure of the image.

1.2. Feature Extraction and Feature Array Generation

For every image which is pre-processed, the below listed features are extracted and the feature coordinates are stored into feature arrays.

- Ridge ending points
- Ridge bifurcation points
- Isolated points
- Crossover points

The features are extracted using crossing number technique. Let the extracted feature arrays are $M_{RE,}$ $M_{RB,}$ $M_{IP,}$ and $M_{CR,}$ where:

M_{RE}: Minutiae point array for Ridge Endings.
M_{RB}: Minutiae point array for Ridge Bifurcations.
M_{IP}: Minutiae point array for Isolated Points.
M_{CR}: Minutiae point array for Crossover Points.

Hence, for every fingerprint image, a collection of four 2 dimensional arrays viz., $M_{RE,}$ $M_{RB,}$ $M_{IP,}$ and $M_{CR,}$ is generated.

It is proposed to create a single array FA for every image by merging all the feature arrays so generated, such that:

$$FA= M_{RE}+M_{RB}+M_{IP}+M_{CR,}$$

Where '+' denotes concatation of arrays. It is to be noted that the total number of arrays generated is equal to n, where n is the number specified by the user.

1.3. Random Key Generation

In the following steps, the previously generated feature arrays (FA,) are used to generate the random key. The functions which are needed are:

- next_prime(arg): returns the immediate next prime number to the argument which is passed.
- sum_of_all(arg1, arg2, …argn): returns the sum of all the arguments passed to the function.
- random_number(arg): creates a random number using the arg value as the seed value.
- Size_of(array): returns the no. of elements in the array.
- xval_FA[i]: returns the x-coordinate value stored in array FA at index i.
- yval_FA[i]: returns the y-coordinate value stored in array FA at index i.

1.3.1. Shuffling of individual feature array

For all the FA arrays, apply the algorithm as stated:

1) Create a random array R of size equal to selected FA array.
2) Calculate seed value S as:
   S=next_prime(Sx)* next_prime(Sy); Where
   Sx=(sum_of_all(x) in FA)
   Sy=(sum_of_all(y) in FA)
3) For j=0 to (size_of_FA-1), Use a random number generator with seed value 'S'
   a. R[j]= random_number(S).
4) For i=0 to (size_of_FA-1), do
   a. Calculate TX and TY as:
      i. TX=xval_FA[i]*R[i]
      ii. TY=yval_FA[i]*R[(size_of_R)-i].
   b. Calculate R[i] = (TX+TY) mod S.
5) Merge all R arrays to create a new array FR.

6) Remove all duplicate elements from FR.

1.3.2. Key array generation using feature array

Create a key array K, of size 1024 elements.

For i=1 to 1023

a. randomly select a value from FR and check if it is there in K,
b. if selected element is in K , goto step a; Else, insert selected value into K[i].

1.3.3. Final Key Generation

Create an array FK of size 1024, and set the values of FK as explained below:

a. For i=0 to 1023
    i. FK[i]=K[i]mod 2.
b. Consider the values in array as bits and the array index as bits position and convert it into hex values.

The above generated random number can also be used as the required large random number for any specific encryption algorithm.

1.4. RSA Key Generation

From the array FK, the key pair for RSA Encryption and Decryption generated are as follows:

1) Create two empty arrays FKP and FKQ of size 512.
2) Insert values of FK from index 0 TO 511 in FKP and 512 to 1023 into FKQ.
3) Convert these array values to decimal values FKPD and FKQD by considering the values in arrays as bits and the array indexes as bits position.
4) Calculate p and q as:
    p= next_prime(FKPD).
    q = next_prime(FKQD).
5) Calculate n=p*q.
6) Calculate $\Phi(n) = (p-1)(q-1)$.
7) For i=255 to 1023
    a. Calculate Temp= $FK[i+512]*2^{512} + FK[i+511]*2^{511} + \ldots + FK[i+1]*2^{1} + FK[i]*2^{0}$.
    b. Calculate e=next_prime(Temp).
    c. If ($e< \Phi(n)$) && $gcd(e,\Phi(n))=1$, break.
8) Calculate $d=e^{-1} \bmod \Phi(n)$.

The above generated keys (e,n), (d,n) can now be used for RSA encryption and decryption respectively.

V. CONCLUSION

For every cryptographic algorithm, keys play an important role. Generally multiple biometrics is used to generate the key. Using multiple biometric modalities needs multiple devices for feature acquisition. The proposed methodology makes use of biometric like fingerprint to generate the key and uses only one device. As randomness is involved at many levels starting from fingerprint selection to key generation, the complexity of key is expected to be high. The generated RSA key pair can be used as any conventional RSA key pair to send and receive encrypted data. The random key generated as FK can be used as large random number for various other cryptographic algorithms which need large random keys.
