Schedulability Analysis for a Combination of Non-Preemptive Strict Periodic Tasks and Preemptive Sporadic Tasks

Mohamed Marouf¹

Abstract: We consider the problem of fixed priority scheduling of non-preemptive strict periodic tasks in conjunction with sporadic preemptive tasks. There are few studies about the scheduling problem combining these two kinds of tasks. Moreover, only few results are available on scheduling non-preemptive strict periodic tasks since their performance analysis gives low success ratios. Also, strict periodic tasks are of great importance since they are in charge for example of sensors/actuators or feedback control functions which are all critical in feedback control systems. Such tasks must have the highest priorities in order to guarantee a correct behavior of the control system. Preemptive sporadic tasks can be used for non-critical functions and have lower priorities. We first investigate the scheduling problem of non-preemptive strict periodic tasks by recalling an existing schedulability condition. This results in defining the first release times of strict periodic tasks can have transient and permanent phases. Then, assuming that some non-preemptive strict periodic tasks have been scheduled, we characterize the release times of the sporadic tasks that maximize their worst case response times. We prove that these release times can be restricted to the permanent phase. Finally, for preemptive sporadic tasks, we extend the classical worst case response time computation to take into account non-preemptive strict periodic tasks.

Keywords: Real-time systems, Preemptive/Non-preemptive scheduling, Strict periods, Sporadic tasks

I. Introduction

We consider the problem of scheduling non-preemptive strict periodic tasks combined with preemptive sporadic tasks. Strict periodic tasks are typically in charge of sensor/actuator or feedback control functions. The freshness of the information they use and/or the reactivity of the system are constrained. Indeed, for such tasks it is important to control their jitters (the difference between the worst case and the minimum response times) to ensure the system's stability [1], [2], [3], [4].

We consider the Fixed Priority (FP) scheduling. We assume that all non-preemptive strict periodic tasks have the same highest fixed priority, whereas preemptive sporadic tasks have lower (distinct) fixed priority than strict periodic tasks. Afterwards, for the sake of clarity, we shall use the term "strict periodic tasks" for "non-preemptive strict periodic tasks", and "sporadic tasks" for "preemptive sporadic tasks".

In section II, we first recall related work for strict periodic and sporadic tasks scheduling, then we give the non-preemptive strict periodic task model. In section III, we recall a necessary and sufficient schedulability condition for non-preemptive strict periodic tasks, and investigate the transient and permanent phases for such tasks. In section IV we show how to determine the worst case scenario for a sporadic task where its Worst Case Response Time (WCRT) can be obtained, in the presence of strict periodic tasks. We prove that these release times belong only to the permanent phase of strict periodic tasks, and thus that the schedulability analysis for sporadic tasks can be restricted to the permanent phase. Finally, for preemptive sporadic tasks, we extend the classical necessary and sufficient schedulability condition based on the worst case response time computation [5] to take into account non-preemptive strict periodic tasks.

II. System Models And Related Work

1.1. Related work

Preemptive scheduling has received considerable attention in thereal-time community. However, we can notice that non-preemptive scheduling has received less attention from the real-time community. Yet, non-preemptive scheduling problems should not be ignored since their resolutions may have great advantages in terms of schedulability. On the other hand, these problems are NP-Hard in the strong sense as Jeffay, Stanat and Martel [6] showed.

Baruah and Chakraborty [7]analyzed the schedulability of the non-preemptive recurring task model and showed that there exists polynomial time approximation algorithms for both preemptive and non-preemptive scheduling. Buttazzo and Cervin [8]used the non-preemptive task model to reduce the jitter of the tasks. A comprehensive schedulability analysis of non-preemptive systems was performed by George, Rivierre, and Spuri in [9]. The main difference between these works and the works proposed in this paper lies in the type of

periods we consider for strict periodic tasks, i.e. strict periods. In the classical periodic model, the difference between the start times of two tasks jobs may vary whereas it must be a constant for strict periodic tasks.

Korst et al. proved in [10] a necessary and sufficient schedulability condition for two tasks which can be generalized for more than two tasks. In [11]Eisenbrand et al. proposed scheduling algorithms in the case of harmonic and non-harmonic strict periodic tasks. We proposed in [12], [13] a schedulability analysis for such tasks.

1.2. Systems models

A non-preemptive strict periodic task τ_i is denoted τ_i (S_i^0 , C_i , D_i , T_i), where:

- S_i^0 is the first release time of τ_i
- C_i the WCET (Worst Case Execution Time) of τ_i
- D_i is the relative deadline of τ_i
- T_i is the strict period of τ_i

The start time of the k^{th} job of a strict periodic task τ_i is given by $S_i^k = S_i^0 + k \cdot T_i$. Fig. 1 shows an example of a strict periodic task.

Fig. 1 model for non-preemptive strict periodic task τ_i (S⁰_i, C_i, D_i, T_i)

A preemptive sporadic task is non-concrete, i.e. its first release time can be chosenarbitrarily. A preemptive sporadic task τ_i is therefore denoted (w.r.t. the strict periodic task model) $\tau_i(C_i, D_i, T_i)$. T_i is the minimum inter-arrival time between two successive jobs of τ_i . We consider the case $D_i \leq T_i$ for sporadic tasks. The scheduling used in this paper is Fixed Priority (FP) scheduling. Tasks in Γ^S have the same highest priority while all tasks in Γ^{NS} have distinct lower priority tasks. Furthermore, we assume that task parameters are integers multiple of the tick time.

III. Scheduling Strict Periodic Tasks

1.3. Necessary and sufficient schedulability condition

For the sake of clarity, we use this notification $g_{i,j}$ for the gcd (Greatest Common Divisor) of two periods T_i , T_j : $g_{i,j}$ =gcd(T_i , T_j). Korst et al. gave in [14] a necessary and sufficient schedulability condition for a task set. It consists of applying a necessary and sufficient condition valid for only two tasks to all possible pairs of tasks.

Theorem1: A task set $\Gamma^{S} = \{\tau_{i}(S_{i}^{0}, C_{i}, D_{i}, T_{i}), I = 1...n\}$ is schedulable if and only if for all pairs of tasks (τ_{i}, τ_{j}) satisfy the condition

$$\operatorname{Ci} \leq (S_j^0 - S_i^0) \operatorname{mod} g_{i,j} \leq g_{i,j} - C_j$$
(1)

Now we characterize the transient and the permanent phases of the schedule considering only strict periodic tasks.

1.4. Transient and permanent phases

The transient phase $\Phi = [0,\phi]$ ends at a time $\phi \ge 0$, which is the smallest time such that the release times obtained in any time interval $[\phi+kL, \phi+(k+1)L[, k\in\mathbb{N}^*, relatively to \phi+kL]$, are the same as those obtained in the time interval $[\phi, \phi+L]$, relatively to ϕ .

By definition, L is the length of the permanent phase. The following theorem gives the time interval corresponding to transient phase obtained for the schedule of strict periodic tasks.

Theorem 2We consider a schedule of strict periodic tasks. The transient phase ϕ of this schedule is the time interval given by: $\Phi = [0,\phi]$, where

$$\phi = Max_{i=1..n}(0, S_i^0 + C_i - T_i)$$
(2)

Proof

 ϕ is the smallest integer such as the first permanent phase $[\phi, \phi+L]$ contains (L/T_i) jobs of each task τ_i . Thus the $(\frac{L}{T_i}-1)^{th}$ job of $\tau_i^{(\frac{L}{T_i}-1)}$ must end its execution before $(\phi+L)$, thus

thus

$$S_{i}^{0} + \left(\frac{L}{T_{i}} - 1\right)T_{i} + C_{i} \le \phi + L$$

$$\phi \ge S_{i}^{0} + C_{i} - T_{i}$$
(3)

As ϕ is the smallest integer which satisfies condition (3) then

$$\varphi = \underset{i=1.n}{\operatorname{Max}}(0, S_i^0 + C_i - T_i).$$

IV. Combining Strict Periodic And Sporadic Tasks

In this section, we study the schedulability of a combination of strict periodic and sporadic tasks. We assume that a set of non-preemptive strict periodic tasks have already been scheduled with the highest priority, and a set of preemptive sporadic tasks is to be scheduled with lower (but different) priorities.

We use the following notations:

- Γ^{s} (resp. Γ^{NS}) denotes the task set corresponding to strict periodic (respectively sporadic) tasks.
- hp^{NS}(i) denotes the set of tasks in Γ^{NS} having higher priority than a task τi in Γ^{NS} .

1.5. Schedulability analysis for sporadic tasks

In order to study the schedulability of sporadic tasks when tasks with strict periods have been scheduled, we have to determine the critical instants for a sporadic tasks where the WCRT can be reached.

It has been proved in [5] that a critical instant occurs when the release time of a sporadic task is equal to the release time of all higher priority tasks. As strict periodic tasks have all higher priority than all the sporadic tasks, we define the set of critical instants Ψ which contains all the start times of the strict periodic jobs in the transient and the permanent phases: $[0,\phi+L[$.

To consider tasks with strict periods, we have to study all cases of release times in Ψ and compute the WCRT of a sporadic task τi when its first release time corresponds to the release time of a strict periodic task. For a sporadic task τi , this results in first releasing, at the release time of a strict periodic task in Ψ all higher priority sporadic tasks than τi at the same time. However, rather than testing all the release times of strict periodic tasks in Ψ , some release times are useless and will be thus removed from Ψ according to lemma 1.

Lemma 1 Consider a sequence of consecutive executions of strict periodic tasks with no slack between the executions. Then only the release time of the first strict periodic task in the sequence should be considered for the computation of worst case response time of a sporadic task.

Proof

Consider a sequence seq of consecutive executions of strict periodic tasks corresponding to a subset of tasks in Γ^{S} . Let 0 be the time origin corresponding to the release time of the first strict periodic tasks in the sequence seq. As sporadic tasks have smaller priority than strict periodic tasks, a sporadic task released at time $T_i \ge 0$ can start its execution only when all strict periodic tasks in seq are completed and will terminate at the same time for any release time T_i belonging to [0, duration(seq)], where duration(seq) is the sum of the execution times of all strict periodic tasks in seq. The response time of a sporadic task is therefore maximum when a sporadic task is released at time 0. Hence the lemma.

Thus, if $\exists S_i^k, S_j^l \in \Psi$ such as $S_i^k \cdot S_j^l = C_j$, then S_i^k is removed from Ψ .

Finally, we limit the release times in Ψ only to the release times of strict periodic tasks in the permanent phase according to lemma 2.

Lemma2 In the set Ψ , only the release times which belong to the permanent phase of strict periodic tasks should be considered to study the WCRT of sporadic tasks.

ProofFor strict periodic tasks, the time interval [L, ϕ +L[in the permanent phase contains the release time pattern corresponding to all the release times of the transient phase [0, ϕ]. The transient phase may contain less jobs than in the permanent phase. Thus, jobs of the permanent phase are more critical than those of the transient phase for sporadic tasks.

The following theorem gives the computational requirements at time t for a sporadic task τi released at time $S \in \Psi$.

Theorem 3 Consider a strict periodic task set Γ^{S} and a sporadic task sethp^{NS}(i) already scheduled. Let τi be a sporadic task released at time $S \in \Psi$. The sum of the computational requirements at time t (w.r.t time S) are given by

$$W_{i}(t) = C_{i} + \sum_{\tau_{j} \in hp} NS_{(i)} \left[\frac{t}{T_{j}} \right] C_{j} + \sum_{\tau_{j} \in \Gamma^{S}} \left[\frac{t - s_{j}}{T_{j}} \right] C_{j}$$
(4)

where s_j is the relative start time S_{jk} according to a release time S given by

$$s_{j} = S_{j}^{0} + \left[\frac{S - S_{j}^{0}}{T_{j}}\right] T_{j} - S$$

$$Proof$$
(5)

Consider that a sporadic task τi is first released at time $S \in \Psi$. The sum of the computational requirements at time t (w.r.t time S) $W_i(t)$ is the sum of the following computational requirements:

- 1. one execution of τi starting at time S: C_i;
- 2. all strict periodic tasks (all with higher priority than τ_i):

$$\sum_{\tau_j \in \Gamma^S} \left[\frac{t - s_j}{T_j} \right] C_j;$$

3. all sporadic tasks with higher priority than τ i:

$$\sum_{\tau_j \in hp^{NS}(i)} \left[\frac{t}{T_j} \right] C_j.$$

The following theorem gives a schedulability necessary and sufficient condition for set of sporadic task.

Theorem 4 Consider a strict periodic task set Γ^{S} already scheduled. A sporadic task set Γ^{NS} is schedulable if and only if

$$\forall \tau_i \in \Gamma^{\text{NS}}: R_i \leq D_i \tag{6}$$

where R_i is the WCRT of $\tau_i \in \Gamma^{NS}$, which is the solution of $R_i = W(R_i)$ computed by iteration.

Proof

The proof is identical to the one given in [5] which states that the Worst Case Response Time of any task should be less than or equal to its deadline.

Example

We use the Rate-Monotonic algorithm to schedule the following tasks. Consider the strict periodic task set $\Gamma^{S} = \{\tau_1(0,1,4,4), \tau_2(1,1,6,6), \tau_3(2,1,12,12)\}$, and the sporadic task set $\Gamma^{NS} = \{\tau_4(2,6,8), \tau_5(2,12,12)\}$ to be scheduled.

For (τ_1, τ_2) , $g_{1,2}=2$ and condition (1) is satisfied:

$$1 \le (1-0) \mod 2 \le 2-1 \Longrightarrow 1 \le 1 \le 1.$$

For (τ_1, τ_3) , $g_{1,3} = 4$ and condition (1) is satisfied:

$$1 \le (2-0) \mod 4 \le 4-1 \implies 1 \le 2 \le 3.$$

For $(\tau_2, \tau_3), g_{2,3} = 6$ and condition (1) is satisfied:

$$1 \le (2-1) \mod 6 \le 6-1 \Longrightarrow 1 \le 1 \le 5.$$

Thus, Γ^{S} is schedulable.

According to theorem 2,the schedule of Γ^{s} has no transient phase. The permanent phase starts at time 0 and has a length L= lcm(T₁,T₂,T₃)= 12, thus Ψ ={0,1,2,4,7,8} corresponding to the release times of tasks Γ^{s} in the time interval [0, L[. After pruning the release times of strict periodic tasks according to lemma 1 we have: Ψ ={0,4,7}.

From theorem 3 we have:

$$W_4(t) = 2 + \left[\frac{t-s_1}{4}\right] + \left[\frac{t-s_2}{6}\right] + \left[\frac{t-s_2}{12}\right],$$

And

$$W_4(t) = 2 + \left[\frac{t}{8}\right] \cdot 2 + \left[\frac{t-s_1}{4}\right] + \left[\frac{t-s_2}{6}\right] + \left[\frac{t-s_2}{12}\right].$$

According to theorem 4, the response times of τ_4 and τ_5 for the release times in SE Ψ are given by:

S	s ₁	s ₂	S ₃	R ₄	R ₅
0	0	1	2	6	12
4	0	3	4	3	7
7	1	0	7	4	9

As $R_4 \le D_4$ and $R_5 \le D_5$, τ_4 and τ_5 are schedulable as shown in Fig.2.

Fig. 2 scheduling diagram of strict periodic and sporadic tasks

V. Conclusion

In this paper we have considered the problem of scheduling, with fixed priorities, strict periodic tasks in conjunction with sporadic tasks. Strict periodic tasks have the highest priority. We first present a necessary and sufficient schedulability condition valid for strict periodic tasks. This results in defining the first release times of strict periodic tasks preserving the strict periodicity constraints. Then, we show that the schedule of strict periodic tasks can have a transient and a permanent phase. We characterize the duration on both phases and show that we only need to consider the permanent phase for the schedulability of sporadic tasks. The release time of sporadic tasks can be chosen arbitrarily. We show that a worst case response time analysis can be used for sporadic tasks. The worst case response time of a sporadic task is obtained by releasing all sporadic tasks synchronously, at the release time of a strict periodic tasks in the permanent phase. We also show how to prune the times to consider (corresponding to the release times of strict periodic tasks) in the permanent phase. We give the schedulability condition for sporadic tasks based on the worst case response time computation of the tasks.
