Abstract: Face recognition is a hot research topic in the fields of pattern recognition and computer vision, which has been found a widely used in many applications, such as verification of credit card, security access control, and human computer interface. As a result, numerous face recognition algorithms have been proposed, and surveys in this area can be found. Although many approaches for face recognition have been proposed in the past, none of them can overcome the main problem of lighting, pose and orientation. For a real time face recognition system, these constraints are to be a major Analysis (PCA). These methods challenge which has to be addressed. In this proposed system, a methodology is given for improving the robustness of a face recognition system based on two well-known statistical modelling methods to represent a face image: Principal Component Analysis. These methods challenge which has to be addressed. In this proposed system, a methodology is given for improving the robustness of a face recognition system based on two well-known statistical modelling methods to represent a face image: Principal Component Analysis. These methods challenge which has to be addressed. In this proposed system, a methodology is given for improving the robustness of a face recognition system based on two well-known statistical modelling methods to represent a face image: Principal Component Analysis.

I. INTRODUCTION

An overview of the face recognition process is illustrated in Fig. 1. In the figure the gallery is the set of known individuals. The images used to test the algorithms are called probes. A probe is either a new image of individual in the gallery or an image of an individual not in the gallery. To compute performance, one needs both a gallery and probe set. The probes are presented to an algorithm, and the algorithm returns the best match between the each probe and images in the gallery. The estimated identity of a probe is the best match.

While there are many databases in use currently, the choice of an appropriate database to be used should be made based on the task given [2]. Some face data sets that are commonly used: Color FERET Database, Yale Face Database, and PIE Database, FIA video Database, CBCL Face recognition Database,
II. GABOR WAVELETS

In face recognition system the feature based method finds the important features on the face and represents them in an efficient way. Physiological studies found that the cells in the human virtual cortex can be selectively tuned to orientation and to spatial frequency. This confirmation that the response of the simple cell could be approximated using 2D gabor filters is given by G. Daugmann [3]. Gabor filters were introduced in image processing because of their biological relevance and computational properties [4, 5]. The kernels of gabor wavelets are similar to 2D receptive field profiles of the mammalian cortical simple cells. These kernels exhibit desirable characteristics of orientation selectivity and spatial locality. The extraction of local features in an image can be effectively done using gabor wavelets. Using Gabor wavelets is robust to illumination, poses and facial expression changes. Considering all Gabor kernels, all the features are concatenated to form a single gabor feature vector. Then this high dimensional gabor vector space is much reduced by applying statistical modeling methods first PCA and then LDA to obtain more independent and discriminating features.

III. PRINCIPAL COMPONENT ANALYSIS

In image recognition and compression, Principal Component Analysis (PCA) is one of the most successful techniques. The large dimensionality of the data space (observed variables) is reduced to the smaller intrinsic dimensionality of feature space (independent variables). This is the case when there is a strong correlation between observed variables and main purpose of using PCA. Using PCA it is capable of transforming each original image of the training set into a corresponding eigenface. The reconstruction of any original image from the training set by combining the eigenfaces is an important feature of PCA which are nothing but characteristic features of the faces. Consequently by adding up all the eigenfaces in the right proportion the original face image can be reconstructed. Each eigenface represents only certain features of the face, which may or may not be present in the original image. If the particular feature is not present in the original image, then the corresponding eigenface should contribute a smaller part to the sum of eigenfaces. If, by contrary, the feature is present in the original image to a higher degree; the share of the corresponding eigenface in the "sum" of the eigenfaces should be greater. So, the reconstructed original image is equal to a sum of all eigenfaces, with each eigenface having a certain weight and this weight specifies, to what degree the specific feature (eigenface) is present in the original image. That is in order to reconstruct the original image from the eigenfaces, building a kind of weighted sum of all eigenfaces is required. By using all the eigenfaces extracted from original images, exact reconstruction of the original images is possible. By choosing only the most important features (eigenfaces) losses due to omitting some of the eigenfaces can be minimized. Suppose there are C classes in the training data. PCA is based on the sample covariance which characterizes the scatter of the entire data set, irrespective of class-membership. The projection axes chosen by PCA might not provide good discrimination power.

The algorithm used for principal component analysis is as follows:

1.1: Mathematics of PCA

A 2-D facial image can be represented as 1-D vector by concatenating each row (or column) into a single column (or row) vector.

1) We assume the training sets of images are \( \Gamma_1, \Gamma_2, \Gamma_3, ..., \Gamma_m \) with each image \( I(x, y) \). Where \( (x, y) \) is the size of the image. Convert each image into set of vectors and new full-size matrix \( (mxp) \), where \( m \) is the number of training images and \( p \) is \( x \times y \) the size of the image.

2) Find the mean face by:
\[
\Psi = \frac{1}{m} \sum I(x, y) \quad \text{where} \quad L: i = 1, ..., ri.
\]

3) Calculated the mean-subtracted face:
\[
<1> = r - \Psi
\]

4) By implementing the matrix transformations, the vector matrix is reduced by:
\[
C_{mm} = A_{mp} X A_{tp} (9) \text{where} \ C \text{ is the covariance matrix and} \ T \text{ is transpose matrix.}
\]

5) Find the eigen vectors \( V_{mm} \) and eigen values \( \lambda_{mm} \) from the \( C \) matrix and ordered the eigen vectors by highest eigen values.

6) Apply the eigen vector matrix, \( V_{mm} \) and adjusted matrix \( D_m \). These vectors determine the linear combinations of the training set images to form the eigen faces.

7) Instead of using \( m \) eigen faces, \( m' \approx m \) is considered as the image vector for each individual or \( m' \) is the total class used for training.

8) Based on the eigen faces, each image has its face vector by
Wk = u(k'r' - 'l'), k = 1, 2, ..., m'.

9) The weights form a feature vector. This feature vectors are taken as the representational basis for the face images with dimension reduced with m.

IV. RESULTS AND DISCUSSION

In this system is tested with YALE face database and its effectiveness is shown in results. The extracted features are used as it is using the above said feature extraction methods and classification is done using eigenvalues and compared with Euclidean distance measure method. The recognition rate is obtained with fixed number of PCA features. The performance comparison with Euclidean Distance Measure Classifier (ED) is shown in Table I.

<table>
<thead>
<tr>
<th>No. of Features</th>
<th>PCA</th>
<th>GABOR + PCA</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>85.0</td>
<td>89.2</td>
</tr>
<tr>
<td>50</td>
<td>82.0</td>
<td>88.5</td>
</tr>
<tr>
<td>60</td>
<td>92.5</td>
<td>94.9</td>
</tr>
<tr>
<td>70</td>
<td>93.2</td>
<td>98.6</td>
</tr>
</tbody>
</table>

Then using graph, the results analysis can be shown below in figure 2.

V. CONCLUSION

In this system, a Gabor feature based method used to eliminate the variations due to pose, lighting and features is used to increase the robustness of the face recognition system. For different scales and orientations of the Gabor filter, the input image is convoluted with gabor filters. Then this convoluted image feature vectors were formulated using PCA method. PCA is used to reduce the high dimensionality of these feature vectors. This discriminant feature space is used as the training feature space for Back propagation Neural Network in the classification stage. The recognition rate high with features extracted from PCA based Gabor methods than simple PCA methods. As the number of features selected in PCA increased, this consecutively also increases the recognition rate. But this in turn increases the computational load.
