Assessment of Functional Lung Impairment in Hypothyroidism

Department of Physiology*, Department of Medicine** RIMS, Imphal, Manipur.

Abstract:

**Aims:** To determine any functional lung impairment amongst patients diagnosed with hypothyroidism by spirometry. **Methods:** 21 hypothyroid subjects with TSH ≥10 mIU/L aged between 18-52 yrs were studied along with 21 healthy controls in the department of Physiology, Regional Institute of Medical Sciences (RIMS), Imphal. Hypothyroid subjects with other conditions/diseases which affect PFT were excluded. Spirometric parameters were conducted by means of computerised spirometer HELIOS 401/701 (RMS, Chandigarh). The spirometric parameters studied are FVC, FEV1, FEV1/FVC, FEF25-75%, PEFR. Unpaired T-test and Pearson correlation was used and P value <0.05 was taken as significance. **Result:** Hypothyroid subjects showed a reduction of the % predicted value of FVC, FEV1, FEF25-75%, PEFR as compared to control subjects even though these values are within the normal values for their age, sex and gender. But the difference is statistically significant only for FVC. And the % predicted value for FEV1/FVC of hypothyroid subjects is found to be significantly increased than the controls. On analyzing and classifying only the hypothyroid subjects based on FVC values, 47% of the hypothyroid subjects were normal while 9% had mild restrictive lung impairment and the rest 43% had moderate to severe restrictive impairment. A negative correlation was found between TSH levels with the spirometric parameters FVC, FEV1, FEV1/FVC and a positive correlation was found between T3 levels with FVC, FEV1, FEV1/FVC. But none of the findings were not statistically significant. **Conclusion:** The pulmonary functions can be affected in hypothyroidism and they show a restrictive pattern of lung impairment. **Keywords:** Spirometer, hypothyroidism, FVC, FEV1, FEV1/FVC

I. Introduction

Hypothyroidism is a relatively common problem worldwide often with insidious onset and is relatively asymptomatic. Respiratory manifestations are seldom the major complaints in hypothyroidism.[1] Lung volumes are usually normal, but few studies have shown findings suggestive of restrictive pattern of impairment. This has been attributed to decreased in both expiratory and inspiratory muscle strength, alveolar hypoventilation due to depression of hypoxic and hypercarbic ventilatory drives and decreased in maximal breathing and diffusing capacity in patients with hypothyroidism.[2-4,7] Weight gain independently of physical activity is frequently associated with hypothyroidism.[8] Most of the restrictive defects seen among these patients has been thought to be a consequence of obesity and microatelectasis.[1] Overt thyroid dysfunction is well recognized to affect weight, but the influence of minor perturbations of thyroid function remains unclear.[5,6]

In this study, spirometry was done to determine any functional lung impairment in hypothyroid patients and to compare with control subjects who are matched for their age and sex. BMI and body fat percentage was also analysed to determine if it has any contribution to the lung impairment if it is indeed present. And also to determined if there is any correlation between the thyroid function with the pulmonary function among the study population.

I. Materials and methods

A cross sectional study done with 21 hypothyroid patients with TSH≥10 mIU/L and 21 apparently healthy subjects within the age groups of 18-52 yrs. It was conducted in the department of Physiology, Regional Institute of Medical Sciences (RIMS), Imphal with the patients recruited from the Medicine Department. Patients with associated conditions which affect pulmonary function test were excluded. Written informed consent was obtained from the participants. The Institutional ethical committee approval was also taken.

All thyroid function tests were performed in one laboratory centre. TSH, free T4 and free T3 were measured by Chemiluminescence. FVC, FEV1, FEV1/FVC, PEFR, FEF25-75% recorded by computerised Spirometer- Helios 401/701 (RMS, Chandigarh). BMI and body fat % was analysed by Tanita Innerscan Body Composition Monitor using the principle of bioelectrical impedance. Statistical analysis was done with SPSS16. Unpaired T-test and Pearson correlation used and P value <0.05 was taken as significance.
II. Results

The basal parameters of the study population is depicted in table 1 along with BMI and body fat percentage. The hypothyroid group comprised of 81% female & 19% male with mean age of 36.6±11.40 years. And the control group comprised of 76% female & 24% male with mean age of 39.95±10.65 years. There was no significant difference between the two groups in these parameters. And there was also no significant difference in the BMI and body fat percentage between the two groups as well.

The spirometric findings of both hypothyroid subjects and controls are given in table 2 and are expressed in predicted percentage. The mean FVC, FEV₁, PEFR, FEF25-75% values are all comparatively decreased as compared to the controls even though these values are within the normal values for their age, sex and gender. But the difference is statistically significant only for FVC. The mean FEV₁/FVC ratio is found to be increased in comparison to the controls and this ratio is found to be statistically significant. Other parameters PEFR and FEF25-75% were also decreased among the hypothyroids as compared to the controls though it was not found to be statistically significant. This table is also represented in the form of bar diagram in figure 1.

Figure 1: Bar diagram showing the spirometric parameters of hypothyroids and controls

On analyzing and classifying only the hypothyroid subjects as per the American Thoracic Society (ATS) guidelines[12], 47% of the hypothyroid subjects were normal while 9% had mild restrictive lung impairment and the rest 43% had moderate to severe restrictive impairment as depicted in the figure 2.
Assessment of Functional Lung Impairment in Hypothyroidism

There is negative correlation between TSH levels with the spirometric parameters FVC, FEV₁, FEV₁/FVC. But a positive correlation between T₄ levels with FVC, FEV₁, FEV₁/FVC. But none of these findings were not statistically significant as depicted on table 3.

III. Discussion

Hypothyroidism can have numerous effects on the respiratory system. Fatigue and dyspnoea on exertion are frequent symptoms. But in the absence of primary respiratory disease, the diminution of the respiratory function in the hypothyroid patients is not significant in most cases. [1]

Nevertheless, it does affect the respiratory system including respiratory muscle weakness, alveolar hypoventilation due to decreased hypoxic and hypercapnic ventilatory drives, upper airway obstruction, central and obstructive sleep apnoea and even pleural effusion. Lung volumes are usually normal or mildly reduced, but maximal breathing capacity and diffusing capacity are usually reduced. [2]

In our study, FVC & FEV₁ values were found to be lower in hypothyroids as compared with controls but it was significant only for FVC. This is in accordance with other study conducted by Valjevac S et al [3] who demonstrated decreased in FVC and FEV₁ among the hypothyroid subjects and suggested that the degree and the duration of thyroid disorders lead to reduced ventilator lung function in patients with thyroid dysfunction. In other studies, there was a significant difference in the lung functions between those subjects not on treatment and those on thyroid hormone replacement therapy and the decreased in these spirometric parameters in hypothyroidism can be corrected by hormone replacement therapy. [4, 9, 10, 11]

Cakmak G et al [5] observed a significant reduction in FVC, FEV₁, FEV₁ %, FEF₂₅-₇₅, FEF₂₅-₇₅% and DLCO in patients with subclinical hypothyroidism as compared with control subjects. Sharifi F [11] et al reported about 87% of restrictive abnormality ranging from mild to moderate grade amongst the hypothyroid subjects which improved significantly on treatment.

The FEV₁/FVC value is significantly increased among the hypothyroid subjects as compared to controls. This together with the decreased in FVC suggests that there is a mild restrictive pattern among the hypothyroid subjects even though the changes in these specific spirometric parameters are not that extreme so as to suggest a diagnosis of restrictive lung disease as per the ATS guidelines. [12] 47% of the hypothyroid subjects were normal while the rest had some restrictive defects ranging from mild to severe lung impairment. One study reported hypothyroidism with hypoxia associated with computed tomographic features suggestive of pulmonary fibrosis that resolved with correction of the hypothyroidism and suggested that fibrotic disease leading to restrictive abnormality can be associated with severe hypothyroidism. [13]

Analysis of changes in pulmonary function is complicated by increased frequency of overweight or obesity in hypothyroid patients. Abnormalities attributed in the literature to hypothyroidism actually may have been due to obesity. [1] But in our study, the average BMI & body fat % of the hypothyroid patients are 24.02±4.4kg/m² & 27.7±9.8% respectively & this are within the recommended range for their age, sex and

wwwioskjournals.org
Assessment of Functional Lung Impairment in Hypothyroidism

gender (Based on NIH/WHO guidelines). And there is no significant difference in terms of the BMI and body fat percentage between the hypothyroid subjects and the controls. Hence, the additive effects of obesity on spirometric parameters can be ruled out.

On analyzing any correlation between the thyroid hormone levels and the pulmonary function amongst the subjects, it is found that there is an inverse correlation between TSH levels with the spirometric parameters FVC, FEV₁, FEV₁/FVC. But a positive correlation was found between T4 levels with FVC, FEV₁, FEV₁/FVC. But none of these findings were not statistically significant. These findings are similar with study conducted by Cakmak et al[4] in which they found negative correlation between TSH levels with FVC, FEF₂₅₋₇₅% and positive correlation between T₄ levels with FCV only.

The decreased in all the values for spirometric parameters in hypothyroid subjects maybe attributed to low serum T₄ which may cause inspiratory muscle power weakness and hypoventilation.

IV. Conclusion

There is a significantly reduction in the dynamic lung functions of hypothyroid subjects as compared with controls. Respiratory system can be affected in hypothyroidism. Simple spirometry can be considered as a means for evaluation of pulmonary functions in these patients.
