Abstract:
Introduction: The major cause of morbidity and mortality in burn patients is due to infections. Inspite of recent advances in the health care practices related to burn wound management and infection control practices, still infection remain the main cause of mortality. Emergence of drug resistant pathogens like MRSA and ESBL producers is leading to inappropriate treatment and hence increased morbidity and mortality.
Aims: To isolate various bacteria from samples of burn wound infections and the antibiotic pattern of the isolated organisms.
Materials and Methods: Swabs from 435 burn wounds received at microbiology laboratory, Andhra Medical College from King Gorge Hospital during the period of June 2014 to June 2015 were included in the study. The samples were processed as per the standard protocol. Pathogenic organisms were isolated, identified by biochemical tests and antibiotic susceptibility testing was performed by Kirby- Bauer disc diffusion method.
Results: Out of 435 samples, 405 (93%) samples were culture positive and 30 (6.9%) were sterile. The predominant isolate was Pseudomonas (33.6%) followed by Escherichia coli (20.9%), Klebsiella species (18.5%), Proteus species (17.3%), Staphylococcus aureus (5.7%) and Acinetobacter species (3.9%). Among Staphylococcus aureus, 39.1% were MRSA and all were susceptible to vancomycin and linezolid (100%). Gram negative isolates were more sensitive to Meropenem (92.6%), Amikacin (92.6%), PIT (86.7%) and Ceftriaxone (86.1%). Extended spectrum Beta lactamase (ESBL) producers were 28% among Enterobacteriaceae isolates.
Conclusion: Continuous microbiological surveillance and careful in vitro testing prior to antibiotic use and strict adherence to hospital antibiotic policy helps in the prevention of emergence of multidrug resistant pathogens like MRSA and ESBL producers.
Keywords: Antibiotic susceptibility, Burns, ESBL, MRSA, Pseudomonas aeruginosa.

I. Introduction
The major cause of morbidity and mortality in burn patients is due to infections. Burn patients are ideal hosts for opportunistic infections. Inspite of recent advances in the health care practices related to burn wound management and infection control practices, still infection remain the main cause of mortality. Several reports states that nearly 75% of all deaths in burn patients are due to infections. Further, infections cause delay in maturation and deep scar formation of burn wounds.
Aerobic bacteria routinely isolated from burn wounds include Pseudomonas aeruginosa, Escherichia coli, Klebsiella spp, Proteus spp, Staphylococcus aureus etc. Pseudomonas aeruginosa has emerged as a predominant member of burn wound flora. The pathogens which cause infections vary from place to place and time to time. Emergence of drug resistant pathogens like MRSA (Methicillin Resistant Staphylococcus aureus) and ESBL (Extended Spectrum Beta Lactamase) producers is leading to inappropriate treatment and hence increased morbidity and mortality.

The present study was conducted to know the current aerobic bacterial profile and their antibioticogram of burn wound infections in a tertiary care hospital.

II. Aims and objectives
1. To isolate various bacteria from samples of burn wound infections.
2. To study the antibiotic pattern of the isolated organisms.

III. Materials and methods
A total of 435 burn wound swabs received at microbiology laboratory, AMC from KGH during the period of June 2014 to June 2015 were included in the study. The samples were collected prior to antibiotic therapy by commercially available sterile swabs and transported to the lab. The samples were processed in the

Bacteriological profile and Antibiogram of Burn wound infections in a tertiary care hospital

laboratory as per the standard protocol by inoculating on Blood agar, MacConkey agar and incubated overnight at 37°C aerobically. Pathogenic organisms were isolated and identified by conventional biochemical tests. The antibiotic susceptibility testing was performed by Kirby- Bauer disc diffusion method as per CLSI guidelines and commercially available antibiotic discs (Hi-media) were used.

For GPC the following drugs were used…
1. Cefoxitin 30 mcg
2. Amoxyclav 20/10 mcg
3. Azithromycin 30 mcg
4. Ofloxacin 5 mcg
5. Vancomycin 30 mcg
6. Linezolid 30 mcg
7. Meropenem 10 mcg
8. Ceftazidine 30 mcg

For GNB the following drug were used
1. Amoxyclav 20/10 mcg
2. Ciprofloxacin 5mcg
3. Amikacin 30mcg
4. Ceftazidime 30 mcg
5. Ceftriaxone 30mcg
6. Piperacillin+ Tazobactum 100/10 mcg
7. Ceftazidime + Clavulanate 30/10 mcg
8. Meropenem 10 mcg

E. coli ATCC 25922, Pseudomonas aeruginosa ATCC 27853, Staphylococcus aureus 25923 were used as control strains.

Cefoxitin disc was used to detect methicillin resistance in Staphylococcus species and ESBL producing organisms were identified by using ceftazidime and ceftazidime + Clavulanic acid discs as per CLSI guidelines IV.

Results

Out of 435 samples, 258 (59.3%) were from females and 117 (40.6%) were from males. Majority of the cases were from 20 to 40 years age group (66%). Out of 435 samples, 405 (93%) samples were culture positive and 30 (6.9%) were sterile.

</table>

Note: AMC = Ciprofloxacin, AK = Amikacin, CAZ = Ceftazidime, CTR = Ceftriaxone, PIT = Piperacillin + Tazobactum, CAC = Ceftazidime + Clavulanic acid, MEM = Meropenem

Gram negative isolates were sensitive to Meropenem (92.6%), Amikacin (92.6%), Ceftriaxone (86.1%) followed by Ceftazidime, Ciprofloxacin and Amoxycilav (86%). Extended spectrum Beta lactamase (ESBL) producers were 28% among Enterobacteriaceae isolates, which was detected by Ceftazidime + Clavulanic acid combination discs as per CLSI guidelines.

### V. Discussion

The rate of nosocomial infections are higher in burn patients due to various factors like nature of burn injury, immunocompromised status of patient, invasive, diagnostic and therapeutic procedures and prolonged ICU stay. In the present study, the incidence of burn wound infection was higher in females (59.3%) which correlates with S. Rajeshwara Rao et al. (56.2%) and Umachowdary et al. (53%) which reported 68%. The common age group affected in the present study was 20-40 yrs (66%) which correlates with Kaur et al. and S. Rajeshwara Rao et al. In the present study, Pseudomonas aeruginosa was the commonest isolate (33.6%) which correlates with Alirej Ekrami et al. (37.5%) and Herjinder Kaur and Mahto et al. (51.5%). The antibiotic sensitivity pattern of Gram negative bacilli and Gram positive cocci in the present study correlates with S. Rajeshwara et al.

Methicillin resistance was seen in 39.1% of Staphylococcus aureus isolates in the present study which coincides with S. Rajeshwara et al. (32.7%) and Alirej Ekrami et al. (58%) and dissimilar in various studies. In the present study, ESBL producers among Enterobacteriaceae were 28% which Correlates with S. Rajeshwara et al. (30.9%) and Alirej Ekrami et al. (32.1%). Among Staphylococcus aureus, 39.1% were MRSA and all were susceptible to vancomycin and linezolid (100%) correlates with S. Rajeshwara et al.

### VI. Conclusion

As infections are serious problem among burn patients, there is a need for every hospital to have a data on prevalent organisms and their antibiotic susceptibility pattern which also helps to formulate an effective antibiotic policy.

Inadequate antimicrobial therapy for infected patients may lead to higher morbidity and mortality but inappropriate use of higher antibiotics leads to MDR strains. Hence continuous microbiological surveillance and careful in vitro testing prior to antibiotic use and strict adherence to hospital antibiotic policy helps in the prevention of emergence of multidrug resistant pathogens like MRSA and ESBL producers.
