Abstract

Aim: This study compares the efficacy of three different retreatment file systems and determines which retreatment file requires less time in removal of previous root filling material.

Methodology: Thirty anterior teeth with single root canal were used in this study. The teeth were randomly divided into three experimental groups of ten specimens each. They were instrumented and obturated using monococone technique with gutta-percha (GP) and sealer.

Removal of gutta-percha was performed with the following devices and techniques: EDGEFILE XR, MTWO, and R-ENDO. For all cases, the following data were recorded: procedural errors, duration of retreatment and canal wall cleanliness which was evaluated using stereomicroscope at 6X magnification. Photographs were taken for further analysis using computer image analysis program. ANOVA test and Bonferroni multiple comparison tests were used for statistical analysis.

Results: No system completely removed the root filling material from root canal walls. EDGEFILE XR retreatment files removed the maximum amount of filling material from the canal walls. The mean operating time was minimum with Mtwo group files.

It was concluded that EDGEFILE XR, rotary retreatment system proved to be the most efficient method of removing gutta-percha and sealer in comparison to the other two retreatment files and M-TWO retreatment files required less time to remove root filling material than the other instruments.

Keywords: EdgeEndoFiles, GuttaPercha, MTwoFiles, R-Endo files, Retreatment, Stereomicroscope.

I. Introduction

Quality of dental care provided to the general population has improved immensely due to advancement in technology. These advancements along with increased dental patient education and awareness, have ensured that the dentition continue to remain a key part of people’s lives. With increased population life span, the need to maintain a dentition for a prolonged period of time has led to a series of advanced dental procedures that were nonexistent few years ago. Therefore the need for conventional root canal therapy has also increased substantially. Root canal treatment has reported a success rate between 62% and 96% over the last few decades. However it is unfortunate that a certain number of endodontically treated teeth have to be retreated. Variety of reasons have been attributed for the failure of root canal treatment, such as poorly treated and obturated canals, complications with respect to instrumentation, over extensions of obturating materials and complicated root canal anatomy.

In 1986, late Dr. Herbert Schilder quoted the term “RETREATODONTICS” and said that the future of endodontics lies in the “Retreatment of Endodontic Failures”. When root canal therapy fails, treatment options include conventional retreatment, periradicular surgery or extraction. Whenever possible, the retreatment option is preferred because it is the most conservative method to solve the problem.[2] The main goals of orthograde retreatment are regaining access to the apical foramen by complete removal of root canal filling materials thus facilitating sufficient cleaning and shaping of the complete root canal system and final obturation.[3,4] Necrotic tissue or bacteria, covered by remaining GP [Gutta Percha] or sealer may be responsible for periapical inflammation or pain. E. faecalis is the main species found in cases of root filled teeth associated with peri-radicular lesions.[1,5,6]

Only if the filling material can be removed completely and the root canal negotiated to the apical foramen, allowing thorough debridement, can the prerequisites for a successful retreatment be fulfilled. [1,4] Several techniques have been proposed to remove filling materials from the root canal system, including the use of endodontic hand files, Nickel-Titanium (Ni-Ti) rotary instruments (Masiero & Barletta 2005, Hammadet al. 2008), Gates Glidden burs, heat, ultrasonic instruments (Wilcox 1989), laser (Viducic et al.2003) and use of adjunctive solvents. Conventionally, the removal of gutta-percha using hand files with or without solvent can be...
a tedious, time-consuming process especially when the root filling material is well compacted (de Oliveira et al. 2006). Therefore, the use of NiTi rotary instruments in root canal retreatment might decrease patient and operator fatigue (Tasdemiret al. 2008a).

Three NiTi systems have recently been introduced: R-Endo (Micro-Mega, Besancon, France), Mtwo (Sweden & Martina, Padova, Italy) and EdgeFile XR (EdgeEndo, USA).

R-Endo retreatment files were used in a gentle in and out motion on the canal walls according to manufacturer’s instruction. A manual file Rm was used first to relocate the canal orifices, then the Re (size 25, 0.12 taper) instrument removed the first 2-3 mm of the filling. R1 (size 25, 0.08 taper) and R2 (size 25, 0.06 taper) were used to one-third and two-thirds of the estimated working length respectively. Finally, R3 (size 25, 0.04 taper) was used at the working length to complete the removal of filling material from the canal. Mtwo Retreatment Files consist of two instruments with active cutting tip: R1 (size 25, 0.05 taper) and R2 (size 15, 0.05 taper) (Somma et al. 2008, Tasdemiret al. 2008a). They have an S-shaped cross-section as do the files of the basic sequence, but a shorter pitch length to enhance the advancement of the file into the filling material. These instruments are characterized by two cutting edges, which are claimed to cut dentine effectively (Gergi & Sabbagh 2007).

Recently, EdgeFile XR retreatment nickel–titanium (Ni–Ti) rotary files that are made of an annealed heat-treated Ni–Ti alloy brand named Fire-Wire™ have been introduced to the market. The deformation and strength characteristics of metals and metal alloys could be changed with heat treatment. According to manufacturer Fire-Wire™ Ni–Ti yields performance-enhancing durability that provides incredible flexibility, so that XR files will enhance and expedite the endodontic retreatment. The cyclic fatigue has been custom tested and found to be twice that of the other file systems. System includes four files – R1 (25/0.12), R2 (25/0.08), R3 (25/0.06), R4 (25/0.04) – that are used in crown-down manner. All files have constant taper and parabolic cross section.

II. Materials and Methods

Selection of teeth: thirty maxillary central and lateral incisors with mature root apices and single canal extracted for periodontal reasons were used. Teeth with root caries, cracks on the root surface, curved roots and extremely calcified canals were excluded. Soft tissue and calculus were removed mechanically from the root surface.

Initial root canal treatment

Each tooth was decoronated at the cemento-enamel junction (CEJ) with a diamond disc to facilitate straight line access for instrumentation and obturation. Proper access was established and the apical patency was determined by inserting an ISO #10 K-file until it appeared at the apical foramen. Working length was determined by placing a size 15 K-file into the canal until it appeared at the apical foramen; this length was measured and the working length was set 0.5 mm short of this distance. A circumferential ‘staging platform’ was established near the canal orifice, ensuring a uniform working length (WL) of 15 mm in each tooth. Cleaning and shaping were performed using a modified step-back flare technique. The coronal third was flared with sizes 1–3 Gates Glidden drills (DentsplyMaillefer). Canal preparation was carried out by the sequential use of K-files (DentsplyMaillefer, Ballaigues, Switzerland) up to size 30 at working length; a step-back procedure in 1 mm increments to a file size 50 was then carried out. Upon withdrawal of each instrument, canals were irrigated alternatively with 5.25% sodium hypochlorite (NaOCl) and 17% ethylenediaminetetraacetic acid (EDTA).

Root canal obturation:

The root canal of each tooth was dried with paper points and obturated with gutta-percha (GP) and sealapex using a cold lateral compaction technique. The coronal access cavities of the specimens were sealed with temporary filling material (Cavit, DeTreyDentsply). The quality of the root fillings was confirmed using postoperative radiographs. All teeth were stored at room temperature for 30 days to allow complete setting of the sealer.

Retreatment Techniques:

All the specimens were randomly divided into three experimental groups (n=3) with 10 specimens each for removal of gutta-percha by using one of the following techniques:

Group A: EdgeFile XR retreatment files
Group B: R-Endo
Group C: M-two retreatment files
All instruments were used in a crown-down technique on a low-torque rotary engine driven motor (X-Smart; DentsplyMaillefer) in the preset torque levels recommended by the manufacturer for each type of instrument, and at a constant speed of 500 rpm.

**Group A: EdgeFileXR**
R1 (25/0.12), R2 (25/0.08), R3 (25/0.06) and R4 (25/0.04) files were used in crown-down manner with light to medium pressure in apical way, respectively. The sequence was repeated until R4 reaches to WL. Final apical preparation was then performed using the EdgeFile X3- C4 file (size 40/0.06 taper). As a safety feature the files are designed to unwind. They may be used until the files unwind backwards.

**Group B: R-Endo**
R-Endo rotary system was used as recommended by manufacturer in crown-down technique and push-and retains motion circumferentially. R1, R2 and R3 were used respectively to remove the root filling material from the coronal, middle and apical thirds. The removal of the obturation material was considered complete when the working length was reached, no material was observed between the flutes of the files, and the walls of the canal were smooth and free of visible debris.

**Group C: M-two**
Retreatment Files (M-two R) were also used according to the instructions of the manufacturer. Root canals were instrumented in a simultaneous technique to the working length using M-two R2 (size 25, 0.05 taper) in a brushing action with lateral pressing movements. Progression of the rotary file was performed by applying slight apical pressure and frequently removing the files to inspect the blades and clean the debris from the flutes. Lastly, conventional Mtwo rotary instrument (size 30, 0.05 taper) was used at WL.

**Evaluation**

**a) Remaining gutta-percha and sealer**

All specimens were rendered transparent according to the following technique described by Schirrmieister et al. 17. The specimens were decalcified in 5% nitric acid for 72 hours, washed for 4 hours and dehydrated in increasing concentrations of alcohol (80%, for 12 hours, 90% for 1 hour and 99% for 3 hours). The roots were cleared subsequently using methysalicylate. The GP/sealer remnants on the canal walls were imaged on a black background in mesio-distal (M-D) direction using a stereomicroscope at 6X magnification. Each canal was divided into coronal, middle and apical thirds from the ‘staging platform’ to the terminus of the apical preparation. The area of GP/sealer remnants as well as the canal wall was measured using image analyzer software.

**b) Operating time**
The operating time which elapsed from initial GP removal with the first instrument until reaching the original working length was recorded as T1. The time required to achieve satisfactory GP removal after reaching the working length was recorded as T2. Total time for treatment was the sum of T1 and T2.

**II. Statistical Analysis**

Analysis of variance (ANOVA) was used to analyze the differences in the percentages of GP/sealer remnants covered area amongst the four groups. One-way ANOVA was applied to compare the operating time amongst the four groups. Bonferroni test was performed as the post hoc multiple comparison method.

**IV. Results**

**a) Remnants of material**

All instruments left filling material inside the root canal. The specimens retreated with the EdgeFile XR left less filling material inside the root canals than other groups but significance difference was found between EdgeFile XR and M-Two, R-Endo and Mtwo (<0.001). (Table I) The comparison of GP/Sealer remnants at different levels among three groups using Bonferroni Method test showed that difference in different levels was found to be maximum between coronal and apical levels (4.062) while it was minimum between coronal and middle levels (1.751).

V. Discussion

The primary reason for a negative outcome following the root canal treatment is the persistence of bacteria within the intricacies of the root canal system. Complete removal of pre-existing filling material from canals is a prerequisite for successful nonsurgical root canal retreatment. This procedure can uncover residual necrotic tissues or bacteria that may be responsible for persistent periodontal inflammation, and allow further cleaning and refilling of the root canal system.

In the present study, the teeth were decoronated to ensure standardization of specimens by eliminating some variables, such as anatomy of the dental crown and access to root canals thereby allowing more reliable comparison between the proposed retreatment techniques. Different methodologies have been reported to evaluate the amount of filling material remaining inside the canal after retreatment procedure. It can be assessed radiographically, roots can be split longitudinally and remaining gutta-percha and sealer were measured linearly or using scoring system or making the teeth transparent. In addition computer tomography and operating microscopes have also been used for this purpose. Ideally, three-dimensional visualization of the root canal system would provide a better understanding of the distribution of the debris after retreatment.

Amongst them, the transparent teeth method is cost-effective and sensitive enough to identify small area of residual GP/sealer on the canal wall. In the present study, the roots were made transparent to allow measurement of the area of residual filling material.

For the present study xylene was selected from a variety of different solvents which are recommended for endodontic retreatment which includes eucalyptol, halothane, methyl chloroform, chloroform, turpentine. Xylene slowly dissolves the gutta-percha, thus allowing better control and removal of softened gutta-percha rather than liquefied gutta-percha. Although chloroform has been shown to be most effective gutta-percha solvent when compared with other solvents but its use is controversial. It has been reported to be locally toxic when in contact with periodontal tissues. Additionally it is hepatotoxic and nephrotoxic and is classified as a carcinogen.

Different methods have been applied to remove root canal filling material from canals. These include use of hand files, ultrasonic files, engine driven instruments and lasers. Conventionally, the removal of gutta-percha using hand files with or without solvent can be a tedious and time consuming process, especially when the root filling material is well condensed. Therefore the use of rotary NiTi instruments in root canal retreatment might decrease patient and operator fatigue. In the current study, all retreatment techniques left GP/sealer remnants within the root canal. This finding confirms previous results reported by numerous investigators using different retreatment instruments, techniques and solvents. Furthermore, the present investigation showed that that rotary NiTi instruments, the EdgeFile XR instrumentation was significantly more effective than Mtwo and R-Endo group in terms of residual material, whereas no statistical difference was found amongst the EdgeFileXR and R-Endo instrumentation group. There have not been sufficient studies comparing the efficiency of the EdgefileXR to other retreatment files conventionally used for retreatment in endodontics. In the present study the better performance of EdgefileXR instruments may be because they are made of an annealed heat treated Ni-Ti alloy brand named Fire-Wire™. The heat treated Fire-Wire™ Ni-Ti yields performance enhancing durability (PED) that provides not only incredible flexibility, but according to the manufacturers it performs much better than other files in cyclic fatigue testing; a key indicator of file strength and durability. Edgefile XR enhances and expedite the re-treatment of a root canal.
Combines the attributes of being a highly efficient and flexible instrument while being extremely safe and resistant to fracture. According to the present study system, R-Endo left almost similar amount of filling material in the canal walls compared with EdgefileXR. Tasdemir et al.16 reported that ProTaper, R-Endo and manual instrumentation groups have similar effectiveness in removing filling material in straight root canals. In the present study significant difference was found between R-Endo group and Mtwo, this is in accordance to the study done by Tasdemir et al.16 The Mtwo instruments have an S-shaped cross-sectioned, an increasing pitch length in the apical-coronal direction which is characterized by positive rake angle with two cutting edges, which are claimed to cut dentin effectively.29 Unlike other NiTi instruments, the Mtwo rotary instruments do not require a crown-down instrumentation sequence. Using the Mtwo instruments with the single length preparation leaves more filling material in the canal during retreatment.

Advantages of rotary files includes maintenance of canal shape, reduced working time and reduced operator fatigue whereas disadvantages includes higher incidence of file separation [28,10], extrusion of obturating material and debris through the apical foramen, alterations of root canal morphology [10], but this study utilized the parameter which is time required for retreatment procedure as criteria for evaluation. It was concluded in this study that rotary instruments were significantly fast in removing gutta-percha, while Mtwo require less time than EdgefileXR and R-Endo rotary instruments. This is due to the specific design of M-two, resulting in aggressive cutting edges and positive rake angle which require less energy to cut dentin. The number of instruments in EdgefileXR and R-Endo also affect the working time even though they are more effective in removal of guttapercha.

VI. Conclusion
Within the parameters of this study, the following conclusions may be drawn:

- None of the techniques removed all filling materials from root canal walls.
- EdgefileXR-re-treatment files and R-Endo re-treatment files left significantly less gutta-percha and sealer than M-two system.
- Re-treatment with M-two system Ni-Ti rotary systems was significantly faster compared to other two rotary techniques used in the removal of gutta-percha/sealer.
