#### Abstract

Introduction: The purpose of this study was to investigate the correlation between vertical facial pattern and dental arch forms in different types of skeletal malocclusion. Materials and Methods: The study comprised of 90 pretreatment (lateral cephalogram, dental cast and photographs) aged between 11-38 years full permanent dentition without agenesis and/or tooth loss except third molar. The evaluation of the dental arch form was performed using a computer analysis (AutoCad). Results: Assessment of interexaminar reliability analysis was performed using Kappa statistic. Pearson correlation was used to analyze the dental arch form and facial vertical dimensions and the differences between the three groups were identified through an analysis of variance (ANOVA). Conclusion: As the form of dental arches is associated with the vertical growth patterns, it would be desirable to use individualized arches for each patient.

Key Words: Reliability, AutoCad, Photographs

## I. Introduction

The determination of dental arch forms is an important aspect of orthodontic treatment. Arch form and arch dimensions are two important factors in case assessment, diagnosis and treatment planning. ${ }^{1}$ The factors that affect a patient's arch form are dental perimeter, arch width, and arch depth which influence the arch form. Arch width is measured as intercanine width, interpremolar width and intermolar width. Transverse expansion can change the arch perimeter along with increase in intercanine and intermolar width. ${ }^{2}$ The form of mandibular dental arch is considered one of the key stone during treatment and its maintenance is an important factor for the stability of orthodontic treatment. Preservation of form and dimensions of dental arches must be one of the first objectives of orthodontic problem. Arch wires are the vital components of fixed orthodontic treatment. ${ }^{3}$ The fabrication of arch form in the canine and molar region should be planned in the proper way so as to prevent the instability of arch form. ${ }^{5-6}$ Orthodontic manufacturer produce different arch forms as archwires and it is difficult to choose the most suitable for our patients. ${ }^{7-8}$ Tsunori et al ${ }^{9}$ reported that, when compared with average and long-face persons, short-face subjects had larger intermolar widths and greater buccal cortical bone thicknesses in the molar area of the mandible. Isaacson et al ${ }^{10}$ reported that subjects with long faces showed decreased maxillary intermolar width. Clinicians often pay much attention to the inclination of the mandibular plane, because it is a major determinant of the vertical dimension of a face. Since, no study had been conducted to evaluate the correlation between vertical facial patterns and dental arch forms in different types of skeletal malocclusion.

## II. Materials And Method

The present study was carried out in the department of Orthodontics and Dentofacial Orthopaedics of Himachal Dental College and Hospital, Sundernagar (H.P). The sample consisted of 90 pretreatment records (lateral cephalogram, dental cast and photographs) aged between 11-38 years and the subjects were included in the study as per the following inclusion and exclusion criteria.

## INCLUSION CRITERIA

a) Full dentition except third molars.
b) Pre-treatment lateral cephalogram, dental casts and digital photographs of dental cast.
c) Individuals between 11-38 years of age.

## EXCLUSION CRITERIA

a) Previous orthodontic treatment
b) Edentulous spaces
c) Malformation

## MATERIALS USED FOR THE STUDY:

1. Radiographs- Lateral Cephalogram.
2. Dental casts and photographs
3. AutoCad Software

## Method of tracing

The radiographic films were covered on one side with the transparent cellulose acetate sheet. The tracings of the films were done using 3 H lead pencil. In the lateral cephalograms, the ANB angle was measured and divided into three groups of 30 each; skeletal Class I, Class II and Class III, according to the Steiner's ${ }^{11}$ ANB angle (Class I- ANB $0^{\circ}-4^{\circ}$, Class II- ANB $>4^{\circ}$, Class III- ANB $<0^{\circ}$ ). The subjects will be further divided into three subgroups according to the values of angle SN-MP according to Schudy ${ }^{12}$ : (1) low angle (MP-SN $<27^{\circ}$ ), (2) average angle (MP-SN $>27^{\circ}$ and $<36^{\circ}$ ), and (3) high angle (MP-SN $>36^{\circ}$ ).

## DENTAL CAST ANALYSIS

Shape of dental arch measurements was performed on digital photographs of patient plaster model. All the photos were taken by a single operator based on American Board of Orthodontics instructions with and the distance from the camera lens to the dental cast was recorded $20-25 \mathrm{~cm}$ for each cast.
The photo files were sent to AutoCad 2013 software. The evaluation of the dental arch form was performed using a computer analysis. The AutoCad software was used to draw a pentagon inscribed inside the arches as shown in figure I for maxilla and figure II for mandible.
The following dental cast landmarks were used:

1. Incisal point: The point in the midway between the incisal edges of two central incisors.
2. Canine point: The cusp tip of right and left permanent canines.
3. Mid central points of first permanent molars: by joining a line diagonally from cusp tip of mesiobuccal cusp to distopalatal cusp and a line from mesiopalatal cusp to distobuccal cusp and mid central point was made at the intersection of these two lines according to author Jucienne Salgado Ribeiro ${ }^{13}$
The following linear measurements were performed on maxillary and mandibular dental casts using computer analysis:
4. Intercanine width The linear distance from cusp tip of one canine to the cusp tip of the other.
5. Intermolar width The linear distance from mid central point of one permanent molar to the mid central point of other permanent molar.
6. The angular measurements were performed on maxillary (Fig. I) and mandibular dental casts (Fig. II) forming a pentagon by using computer analysis. A vertex of the pentagon was placed between the two central incisors; two other vertices lie on the cusp of the canines, and the other two are placed at the center of first molars. Internal angles of the pentagon were measured as shown in Fig I and II.
The angular measurements (Ang1, Ang2R, Ang2L) representing the anterior arch form and angular measurements (Ang3R, Ang3L), representing the posterior arch form were evaluated. The ratio between the intercanine distance and the intermolar distance was calculated. The analysis was performed on both dental arches, the upper and lower, in an independent manner. All the linear and angular measurements on the digital photographs of the plaster models and lateral cephalogram were made twice by same examiner to minimize the error of measurements. Assessment of interexaminar reliability analysis was performed using Kappa statistic. The interexaminer reliability was found to be Kappa $=.80-1.00(\mathrm{p}<0.001)$ which shows perfect agreement according to Landis and Koch(1977). Pearson correlation was used to analyze the dental arch form and facial vertical dimensions in different types of malocclusions using SPSS (Statistical package for social sciences) software. The differences between the three groups were identified through an analysis of variance (ANOVA).

## III. Results

The present study was conducted in the department of orthodontics and dentofacial orthopedics in Himachal Dental College, Sunder Nagar. The correlation between vertical facial pattern and dental arch form in class I, class II and class III malocclusion was investigated. The results were analyzed using ANOVA (analysis of variance). All statistical analysis was performed using the SPSS software package program.
Table I, II and graph I, II shows the mean, the standard deviation, the standard error, the minimum and maximum value of different parameters of class I malocclusion in three different groups divided based on SNMP angle (Low, medium and high angle).

The mean value of angle Ang I in class I maloclussion in different vertical facial patterns was 132 in low angle, 128.60 in average angle and 126.60 in high angle in maxillary arch and 138 in low angle, 132 in average angle and 128.1 in high angle in mandibular arch.
The mean value of angle Ang 2R in class I maloclussion in different vertical facial patterns was 127.9 in low angle, 130.90 in average angle and 132.1 in high angle in maxillary arch and 128.2 in low angle, 130.70 in average angle and 133.5 in high angle in mandibular arch.
The mean value of angle Ang 2L in class I maloclussion in different vertical facial patterns was 126.5 in low angle, 132.70 in average angle and 134.5 in high angle in maxillary arch and 126.9 in low angle, 133.50 in average angle and 136.4 in high angle in mandibular arch.
The mean value of angle Ang 3R in class I maloclussion in different vertical facial patterns was 75.5 in low angle, 73.50 in average angle and 79.1 in high angle in maxillary arch and 69.80 in low angle, 72.10 in average angle and 71.1 in high angle in mandibular arch.
The mean value of angle Ang 3L in class I maloclussion in different vertical facial patterns was 76.3 in low angle, 72.80 in average angle and 75.5 in high angle in maxillary arch and 66.90 in low angle, 71.20 in average angle and 69.7 in high angle in mandibular arch.
The mean value of intercanine distance in class I maloclussion in different vertical facial patterns was 39.96 in low angle, 34.83 in average angle and 37.87 in high angle in maxillary arch and 28.67 in low angle, 27.72 in average angle and 26.85 in high angle in mandibular arch.
The mean value of intermolar distance in class I maloclussion in different vertical facial patterns was 51.77 in low angle, 49.93 in average angle and 49.94 in high angle in maxillary arch and 45.56 in low angle, 44.06 in average angle and 43.81 in high angle in mandibular arch.
Table III AND IV shows the comparision of mean of different parameters of class I malocclusion in three different groups divided based on SN-MP angle (Low, medium and high angle) by one way ANOVA analysis.

Table V, VI and Graph III, IV shows the mean, the standard deviation, the standard error, the minimum and maximum value of different parameters of class II malocclusion in three different groups divided based on SNMP angle (Low, medium and high angle).
The mean value of angle Ang I in class II maloclussion in different vertical facial patterns was 124.43 in low angle, 120.71 in average angle and 120.66 in high angle in maxillary arch and 134.29 in low angle, 131.29 in average angle and 134.71 in high angle in mandibular arch.
The mean value of angle Ang 2R in class II maloclussion in different vertical facial patterns was 123.14 in low angle, 130.57 in average angle and 132.57 in high angle in maxillary arch and 138.57 in low angle, 123.43 in average angle and 132.43 in high angle in mandibular arch.
The mean value of angle Ang 2L in class II maloclussion in different vertical facial patterns was 112.14 in low angle, 128.86 in average angle and 133.43 in high angle in maxillary arch and 138.86 in low angle, 131.14 in average angle and 127.29 in high angle in mandibular arch.
The mean value of angle Ang 3R in class II maloclussion in different vertical facial patterns was 76 in low angle, 79.29 in average angle and 74.29 in high angle in maxillary arch and 68.29 in low angle, 72.43 in average angle and 69.29 in high angle in mandibular arch.
The mean value of angle Ang 3L in class II maloclussion in different vertical facial patterns was 80.14 in low angle, 79.14 in average angle and 77.86 in high angle in maxillary arch and 69.29 in low angle, 73 in average angle and 74.86 in high angle in mandibular arch.
The mean value of intercanine distance in class II maloclussion in different vertical facial patterns was 38.07 in low angle, 35.28 in average angle and 34.77 in high angle in maxillary arch and 26.02 in low angle, 27.25 in average angle and 28.41 in high angle in mandibular arch.
The mean value of intermolar distance in class II maloclussion in different vertical facial patterns was 47.72 in low angle, 44.87 in average angle and 46.67 in high angle in maxillary arch and 41.38 in low angle, 40.67 in average angle and 43.74 in high angle in mandibular arch.
Table VII AND VIII shows the comparison of mean of different parameters of class II malocclusion in three different groups divided based on SN-MP angle (Low, medium and high angle) by one way ANOVA analysis
Table IX, X and Graph V, VI shows the mean, the standard deviation, the standard error, the minimum and maximum value of different parameters of class III malocclusion in three different groups divided based on SNMP angle (Low, medium and high angle).
The mean value of angle Ang I in class III maloclussion in different vertical facial patterns was 140.6 in low angle, 136.6 in average angle and 132.8 in high angle in maxillary arch and 140.38 in low angle, 135.88 in average angle and 134.62 in high angle in mandibular arch.
The mean value of angle Ang 2R in class III maloclussion in different vertical facial patterns was 128.60 in low angle, 129.70 in average angle and 129.90 in high angle in maxillary arch and 130.12 in low angle, 136.38 in average angle and 138.50 in high angle in mandibular arch.

The mean value of angle Ang 2L in class III maloclussion in different vertical facial patterns was 125.40 in low angle, 138.40 in average angle and 131.30 in high angle in maxillary arch and 133.38 in low angle, 133.75 in average angle and 136.62 in high angle in mandibular arch.
The mean value of angle Ang 3R in class III maloclussion in different vertical facial patterns was 77.20 in low angle, 72.2 in average angle and 73.80 in high angle in maxillary arch and 68.62 in low angle, 64.0 in average angle and 76.25 in high angle in mandibular arch.
The mean value of angle Ang 3L in class III maloclussion in different vertical facial patterns was 79.10 in low angle, 69.20 in average angle and 75.90 in high angle in maxillary arch and 70.12 in low angle, 62.12 in average angle and 72.75 in high angle in mandibular arch.
The mean value of intercanine distance in class III maloclussion in different vertical facial patterns was 39.39 in low angle, 32.97 in average angle and 38.96 in high angle in maxillary arch and 29.69 in low angle, 27.51 in average angle and 25.03 in high angle in mandibular arch.
The mean value of intermolar distance in class III maloclussion in different vertical facial patterns was 51.51 in low angle, 49.11 in average angle and 50.07 in high angle in maxillary arch and 48.46 in low angle, 46.88 in average angle and 42.03 in high angle in mandibular arch.

Table XI AND XII shows the comparison of mean of of different parameters of class III malocclusion in three different groups divided based on SN-MP angle (Low, medium and high angle) by one way ANOVA analysis.

Table XIII shows the pearson correlation between the dental arch form and vertical facial pattern in skeletal class I, class II and class III malocclusions.
In class I malocclusion the angle that express the anterior arch form in maxillary arch Ang 1was correlated with the vertical facial pattern. The value of Ang 1 was significant with negative relationship showing $r=-844$ and $p-$ value .002 . The value of Ang 2 R was also highly significant with positive relationship showing $\mathrm{r}=.852$ and p value .002. The value of Ang 2 L was also significant with possitive relationship showing $\mathrm{r}=.791$ and p value .003. The value of Ang 3R and 3L were insignificant with positive relationship showing $r=.691$ and $p$ value .052 and $\mathrm{r}=.586$ and p value .186 . The value of intercanine and intermolar distance ratio was insignificant with negative relationship showing $r=-510$ and p .129 .
In class II malocclusion the angle that express the anterior arch form in maxillary arch Ang 1was correlated with the vertical facial pattern. The value of Ang 1 was significant with negative relationship showing $r=-816$ and $p-$ value . 003. The value of Ang 2 R was also highly significant with positive relationship showing $\mathrm{r}=.837$ and p value .003. The value of Ang 2L was also significant with positive relationship showing $r=.860$ and $p$ value .001. The value of Ang 3R and 3L were insignificant with positive relationship showing $r=.643$ and $p$ value .056 and $r=.570$ and $p$ value .132 respectively. The value of intercanine and intermolar distance ratio was significant with negative relationship showing $\mathrm{r}=-864$ and p .012 .
In class III malocclusion the angle that express the anterior arch form in maxillary arch Ang 1was correlated with the vertical facial pattern. The value of Ang 1 was insignificant with negative relationship showing $r=-650$ and p -value .051 . The value of Ang 2 R was also insignificant with positive relationship showing $\mathrm{r}=.587$ and p value .121. The value of Ang 2L was insignificant with positive relationship showing r $=.362$ and $p$ value .304 . The value of Ang 3R and 3L were insignificant with positive relationship showing r = . 359 and $p$ value .370 and $r=.304$ and $p$ value .472 respectively. The value of intercanine and intermolar distance ratio was insignificant with negative relationship showing $r=-441$ and $p .202$.
In mandible when the when angular(Ang 1, Ang 2R, Ang 3R and Ang 3L) and intercanine to intermolar distance ratio values were correlated with the vertical facial patterns in class I, class II and class III malocclusion, the value of Ang 1 was significant with negative relationship showing $r=-710$ and $p$-value $.023, r$ $=-790$ and $p$-value $.003, r=-629$ and $p$-value .013 respectively. The value of Ang 2R, Ang 2L, Ang 3R, Ang 3L and intercanine to intermolar distance ratio were statistically insignificant.

## IV. Discussion

Information regarding arch dimensions in human populations is important to clinicians in most of the dental specialties including orthodontics. Arch dimensions are also modified by the various arch wires used during treatment affecting the stability of the results achieved. Stability of arch form is one of the most desirable goals of orthodontics, yet unfortunately it is the least understood goal. The size and shape of arches have a
considerable clinical implication in orthodontics specially during diagnosis and treatment planning, as it affects the space available, dental esthetics and stability of dentition. Information regarding arch dimensions in human populations is important to clinicians in most of the dental specialties including orthodontics.
Arch dimensions are also modified by the various arch wires used during treatment affecting the stability of the results achieved. Stability of arch form is one of the most desirable goals of orthodontics, yet unfortunately it is the least understood goal. The size and shape of arches have a considerable clinical implication in orthodontics specially during diagnosis and treatment planning, as it affects the space available, dental esthetics and stability of dentition.

In the present study, the shape of dental arch was measured on the digital photographs of the patient plaster model by drawing a pentagon inscribed inside the arches. The various internal angles inside the maxillary and the mandibular arches of pentagon (Ang 1, Ang 2R, Ang 2L, Ang 3R and Ang 3L) and the ratio between the intercanine and intermolar distance was calculated to evaluate the form of dental arch in different types of skeletal malocclusion.

In present study, value of Ang1in skeletal class I malocclusion was decreased from low angle to high angle (TABLE I, TABLE II and GRAPH I, II). This is in accordance with the study conducted by Al-Taee and Al-Joubori. ${ }^{14}$ When angle Ang 2R, Ang 2L, Ang 3R and Ang 3L were evaluated in skeletal class I malocclusion, it was found that the angular values were increased from low to high angle cases. This is in accordance with the study conducted by Tsunori M, Mashita M, Kasai K $^{15}$ (1998) who evaluate the comparison between average, short and long-face persons. It was concluded that short-face subjects had larger intercanine and intermolar widths and this was the reason that the value of Ang 2R, Ang 2L, Ang 3R and Ang 3L increases from low to high angle case. Also Isaacson et al. ${ }^{16}$ reported that subjects with long faces showed decreased maxillary intermolar width. This is also with accordance with Nasby et al. ${ }^{17}$ who noted increased mandibular molar diameters and length of maxillary and mandibular arches in subjects with reduced Sellanasion/mandibular plane angle (SN-MP).

In present study value of Ang 1in skeletal class II malocclusion was decreased from low angle to high angle cases (TABLE V, TABLE VI and GRAPH II, GRAPH III). This is because of downward and backward rotation of the mandible in hyperdivergent facial patterens. This is also in accordance with the study conducted by Kou Xi $\mathbf{H}^{\mathbf{1 8}}$ who found that the upper and lower incisors of class II, Division 1 malocclusion were labially inclined in vertical growth pattern. When angle Ang 2R, Ang 2L, Ang 3R and Ang 3L were evaluated in skeletal class I malocclusion, it was found that the angular values were increased from low to high angle cases. This may be because as the value of angle Ang 1 decreases, the value of Ang 2R, Ang 2L, Ang 3R and Ang 3L increases shown in figI.

In this study when the internal angles in the maxillary arch were evaluated in different types of skeletal malocclusion, it was found that the value of Ang1was highest in class III malocclusion followed by class I and least in class II malocclusion (TABLE IX, TABLE X and GRAPH V, GRAPH VI). This is because of square arch form in class III malocclusion and narrower arch form in class II malocclusion. This is in accordance with the study conducted by Ricketts et $\mathrm{al}^{19}$ who believed that the brachyfacial hypodivergent face have relatively broader dental arches. The result of present study is in the favour of study conducted by Kageyama et al ${ }^{20}$ who also found narrow arches in hyperdivergent facial pattern.

When angle Ang 2R, Ang 2L, Ang 3R and Ang 3L were evaluated in different types skeletal malocclusion, it was found that the angular values was highest in class III malocclusion and least in class II malocclusion. This is because as value of Ang 1 increases in class III malocclusion results in decreased value of other angles(Ang 2R, Ang 2L, Ang 3R and Ang 3L). Similarly when value of Ang 1 decreases in class II malocclusion results in increased value of other angles(Ang 2R, Ang 2L, Ang 3R and Ang 3L). Only the mandibular arch angular value Ang 1 showed a statistical significant value ( $p<0.05$ ), while values Ang 2R, Ang 2L, Ang 3R, and Ang 3L were not significant in the lower jaw. When different types of vertical facial growth pattern was compared between different skeletal malocclusion, it was found that angular value increased from low to high angle group irrespective of skeletal malocclusion.

The intercanine and intermolar width was found to be increased in skeletal Class III malocclusion followed by class I and least in class II malocclusion. This is in accordance with the study conducted Braun et $\mathrm{al}^{4}$ who found that class III maxillary dental arch widths were an average of 5.1 mm wider (begins in lateral incisor-canine area) and mandibular dental arch width on an average 2.1 mm greater (begins in premolar area) than the arch widths of class I malocclusion. This is in accordance with the study conducted by Staley et al ${ }^{\mathbf{2 1}}$ who also reported that subjects with normal occlusion had larger maxillary molar widths and intermolar widths differences than subjects with class II malocclusion. The increase in intermolar width in class III malocclusion is due to lingual tipping of the anterior teeth in class III development and flattening of the anterior area besides the lateral growth of tongue due to decrease of molar depth. Also this might be due to the anteroposterior skeletal discrepancy and the fact that the mandibular arch is advanced relative to the maxillary arch. The
possible reason for the narrower arches in class II may be due to palatal movement of maxillary posterior teeth which were needed to compensate for the increased overjet and to have good posterior interdigitation.

When different types of vertical facial growth pattern was compared between different skeletal malocclusion, it was found that the intercanine and intermolar width and ratio value decreased from low to high angle group irrespective of skeletal malocclusion. This is in accordance with the study conducted by Ricketts et al ${ }^{18}$ who believed that the brachyfacial hypodivergent face have relatively broader dental arches. Khera AK et al ${ }^{22}$ who also found that the maxillary intercanine width, mandibular intercanine width and first interpremolar width were higher in the hypodivergent as compared with hyperdivergent in males.

When dental arch forms were correlated with different vertical facial patterns the result analysis showed a change in upper arch shape with an intercanine diameter proportionately smaller in patients with high angles and greater in patients with low angles ( $\mathrm{P}<0.05$ ) irrespective of malocclusion. There was no statistically significant difference in mandibular arch forms between the three groups with the exception of the angle value Ang. 1. The bigger the SN-MP angles were, the narrow is the form of the upper arches. Although the data from the present study showed an inverse trend between SN-MP angle and dental arch widths and it seems that the SN-MP angle might be only one of the contributing factors. The decrease of this value from low- to high-angle groups should be interpreted as the prevalence of ' V ' shapes arch form in subjects with high angle and of ovoid arch forms in low angle patients. The data from this study showed an inverse relationship between MP-SN angle and it seems the MP-SN angle might be only one of the contributing factors.

The relationships between the vertical facial morphology and dental arch widths in untreated Himachali adults have an inverse relationship as in Caucasian population. Hence, irrespective of ethnicity and race of the population group, SN-MP and inter-arch widths can be used as a valuable tool in assessing the vertical and transverse craniofacial and dentoalveolar morphology. Hence, the prediction of dental arch width is generalized and can be influenced by other factors.

This highlights the importance of using individualized archwires according to pretreatment arch form and width for each patient during orthodontic treatment. Since the wide variations in patient arches cannot be met by the few preformed archwire shapes and sizes available, the concept of individualization of archwires is strongly suggested.

## V. Conclusion

The conclusions drawn from the study were as follows:

1. When correlation was done between dental arch form and vertical facial pattern in different types of sagittal skeletal malocclusion, it was found to be highest in class I malocclusion followed by class II and least in class III malocclusion.
2. Inverse correlation was found between dental arch form and vertical facial pattern indicating narrower arch form in high angle cases and wider arch form in low angle cases.
3. Intercanine and intermolar distance was found to be highest in class III malocclusion and least in class II malocclusion.
4. As the form of dental arches is associated with the vertical growth patterns, it would be desirable to use individualized arches for each patient.
