Abstract

Introduction: Osteoarthritis (OA) is a chronic degenerative joint disease and a major cause of disability in the elderly people. The rapid increase in the prevalence of this disease suggests that OA will have a growing impact on health care and public health systems in the near future.

Materials and Methods: We conducted a prospective analysis of 40 cases of osteoarthritis knee patients at a tertiary care centre Dr Lals Hospital, Kadru, Ranchi over a period of two years. Those patients who underwent total knee arthroplasty were assessed clinically and functionally using knee society score.

Results: The majority of the patients were from the age group of 56-65 years which accounts for 57.5% of patients in our study. The youngest patient was 48 years of age and the oldest patient was 70 years. The mean age was 60 years.

Conclusion: Total knee arthroplasty improves the functional ability of the patient and the ability of the patient to get back to pre-disease state, which is to have a pain free mobile joint, as reflected by the improvement in the post-op knee clinical score and knee functional score.

Key Words: Osteoarthritis, Total knee arthroplasty

I. Introduction

In most arthritic knees, some degree of instability, deformity, contracture or combination of these elements, can be found. The common causes of arthritis of the knee include osteoarthritis (OA), rheumatoid arthritis (RA), juvenile rheumatoid arthritis, post traumatic arthritis or secondary osteoarthritis and other types of inflammatory arthritis.1

Osteoarthritis (OA) is a chronic degenerative joint disease and a major cause of disability in the elderly people.4 the rapid increase in the prevalence of this disease suggests that OA will have a growing impact on health care and public health systems in the near future.2

The joints most commonly involved include the hip; knee; distal interphalangeal, proximal interphalangeal, and first carpometacarpal joints of the hand; and cervical, thoracic, and lumbar spine. The concept of improving knee joint function by modifying the articular surfaces has received attention since the 19th century.3

The surgical techniques has varied from soft tissue interposition arthroplasty to resection arthroplasty to surface replacement arthroplasty. In surface replacement arthroplasty different types of prosthesis were developed to address the complex knee kinematics.4

The knee society score system is subdivided into a knee score that rates only the knee joint itself and a functional score that rates the patient’s ability to walk and climb stairs. The dual rating system eliminates the problem of declining knee scores associated with patient infirmity.5

The aim of this study was to study the clinical and functional outcome of total knee arthroplasty using knee society score and to find association between knee functional score and knee clinical score.

II. Materials And Methods

We conducted a prospective analysis of 40 cases of osteoarthritis knee patients at a tertiary care centre Dr Lals Hospital, Kadru, Ranchi over a period of two years. Those patients who underwent total knee arthroplasty were assessed clinically and functionally using knee society score.

Inclusion criteria

Moderate to severe knee pain, angular knee deformity, knee stiffness (extension lags and flexion contractures) with decreased range of motion, unilateral/bilateral knee involvement.
Exclusion criteria

Active infection of knee or anywhere in the body, revision arthroplasty, young patients less than 45 years of age, vascular problems (deep vein thrombosis), having periprosthetic fracture, previous implant in knee joint, MRSA positive patients, secondary osteoarthritis-posttraumatic/post inflammatory/post infection, patients not consenting for the study.

Once the patients agreed to participate, informed consent was taken and the subjects were then included in the study. Detailed history of all patients was taken. All patients were assessed clinically and functionally using the knee society score. The preoperative medical evaluation of all patients were done to prevent potential complications that can be life-threatening or limb threatening. Any limb length discrepancies were noted. Presence of any hip and foot deformities was assessed. The extensor mechanism was assessed for any quadriceps contractures. The knee deformities were examined for any fixed valgus deformities or presence of any fixed flexion contracture.

Thorough preoperative evaluation was done of all patients. Total knee arthroplasty was performed by same surgical team under general or regional anesthesia, patient in supine position with knee flexed to 90 degree. Pneumatic tourniquet was used for all the patients to stop blood flow during the surgery, while suction drain was applied after the surgery. After completion of surgery the patient’s knee was immobilised in a Jones compressive bandage and a knee immobiliser immediately post operatively. The patients were started on IV antibiotics and DVT prophylaxis in the form of subcutaneous low molecular weight heparin.

Passive movements and weight bearing were started in all patients 2 days after the surgery, when the drain was taken out. The patient was assessed 3 weeks post operatively for any signs of hematoma or other operative consequences like infection. Once postoperative infection was ruled out clinically the patient was assessed clinically, functionally and using the knee society score at an interval of 1, 3 and 6 months.

Statistical analysis

Descriptive data are expressed as frequency and percentages, and means with SD. A value of p <0.05 was considered statistically significant. Statistical analyses were performed using SPSS 20.0.

III. Results

The majority of the patients were from the age group of 56-65 years which accounts for 57.5% of patients in our study. The youngest patient was 48 years of age and the oldest patient was 70 years. The mean age was 60 years.

There was a male predominance with male female ratio of 2:1 in our study, accounting for 65% of the patients. The mean preoperative knee clinical score (KCS) was 49.40±13.79 which was increased to an average postoperative score of 86.08±5.64 at the end of 6 month as given in Table 1. According to the knee society clinical scoring system of the 40 patients assessed in this study 32 patients (80%) had excellent, 5 patients (12.5%) had good, 2 patients (5%) had fair and 1 patient (2.5%) poor results as shown in Table 2. Similarly the mean preoperative knee functional score (KFS) was 32.75±11.79 which was increased to an average postoperative score of 84.43±9.59 at the end of 6 month as seen in Table 1 and according to the knee society functional scoring system, 30 patients (75%) had excellent, 6 patients (15%) had good, 3 patients (7.5%) had fair and 1 patient (2.5%) poor results as in Table 3.

There was significant increase in KCS and KFC score during follow up at 1, 3 and 6 month interval. One patient (5%) developed infection post operatively. Association between knee functional score and knee clinical score was done preoperatively at 1, 3 and 6 month with Spearman rank correlation coefficient. Spearman 'r' value was 0.418, 0.516, 0.451, 0.717 (p < 0.05).

IV. Discussion

In our study, 56 to 65 years (57.5%) was the most common age group followed by 45 to 55 years (37.5%) with male predominance. This is in accordance to study conducted by Wood et al.6

The knee society score is used to assess the outcome of total knee arthroplasty. The knee society score ratingsystem is a logical outgrowth of the hospital for special surgery rating system. In our study, on clinical functional evaluation of the patients, assessed by the KSS score significant improvement was observed in both KCS and KFS score during follow up at 1, 3 and 6 months compared to preoperative value. There was significant association between KFS and KCS at every interval.7

Similarly in the study conducted by Farahini et al significant improvement in knee society score was observed.16 Our findings also correlates well with study conducted by Yaratapalli et al showing increased in Kneesociety score after TKA.8

In our study, only one (5%) patients showed postoperative infection leading to poor KCS and KFS score in this patient. Buz-Swanik et al, found that after total knee arthroplasty, most of the patients were able to reproduce joint position and significant improve in mobility was observed. These changes may result due to retensioned capsuloligamentous structures and reduced pain and inflammation. There was also significant improvement im the balance index postoperatively. The group treated with the posterior stabilized prosthesis more accurately reproduced joint position when the knee was extended from a flexed position. Retention of the posterior cruciate ligament does not appear to significantly improve proprioception and balance compared with those functions in patients with a posterior stabilized total kneedesign.9

Barrack et al found that total knee arthroplasty with retention of the patella yielded clinical results that were comparable with those after total knee arthroplasty with patellar resurfacing.19 Barrack et al concluded that postoperative anterior knee pain is related either to the component design or to the details of the surgical technique, such as component rotation, rather than to whether or not the patella is resurfaced.

Wood et al concluded that total knee arthroplasty with patellar resurfacing exhibited inferior clinical results as compared to total knee arthroplasty with patellar retention. Total knee arthroplasty with patellar resurfacing exhibited significant limitation of knee extension, which was significantly associated with the presence of post-surgery anterior knee pain. In our study, none of the patellae were resurfaced. All patellas were circumferentially denervated. None of the patients reported anterior knee pain in our study.10

V. Conclusion

Total knee arthroplasty is a relatively safe and sure procedure in the hands of the experienced surgeons. Treatment with total knee arthroplasty resulted in greater pain relief and functional improvement after 6 months. It improves the functional ability of the patient and the ability of the patient to get back to pre-disease state, which is to have a pain free mobile joint, as reflected by the improvement in the postoperative knee clinical score and knee functional score. There was significant association between the knee clinical score and knee functional score at six months follow up where Knee clinical score improved up to 86.08 and functional score up to 84.43.
