The Effect of Inflation and Financial Deepening on Output
Growth: A Cointegration and ECM Approach for Nigeria

Fasoranti M. M., Ph.D and *2R. Santos Alimi
Economics Department, Adekunle Ajasin University, Ondo State, Akungba-Akoko, Nigeria.

Abstract: This study aimed at empirically exploring the triangle of relationships – finance-inflation-growth – with the broader data sets (1970 - 2012) to see whether a direct effect of inflation on growth can be identified as well as an indirect effect through financial sector development. It also seeks to explore the relative strength of the variables in affecting economic growth using the variance decompositions (VDCs) and the impulse-response functions (IRFs) based on the structural vector autoregression (VAR) framework. We found that both Engel-Granger and Johansen cointegration trend suggest that the variables are cointegrated. Based on the existence of cointegration relationship among the variables, we therefore estimate the long-run relationships using the Stock-Watson’s dynamic ordinary least squares (DOLS) model. The results of DOLS model provide an indication that inflation effect on growth is independent of financial development while the financial development effect on growth is dependent of inflation. Furthermore, we also found no evidence of short run causality between RGDP and INF; and there is existence of short run interaction between RGDP and FD that is a bi-directional causality between the variables. Variance decompositions (VDCs) results revealed the variations in the economic growth in Nigeria respond more to shocks in trade openness and next government spending, however, the variations in the economic growth rely more on its own innovations. The policy implication of this finding is for policy makers to develop strategy that will holistic reforms in the financial system and enhance stock market development along side with banking financial institutions. Finally, since financial development effect on growth is dependent of inflation, policy that will ensure price stability will promote output further.

I. Introduction

The role of financial institutions in economic growth has attracted the attention of researchers and policymakers in recent times. There is a large body of literature, both empirical and theoretical, which have examined this issue. The findings of these studies have been controversial. While some studies find that financial sector development has been instrumental in accelerating economic growth, others have suggested that it has not been very significant. Levine (2005) and Beck (2009) for instance, argued that the positive effect of financial development on economic growth can be explained by five mechanisms, whose operations reduce the negative impact of information asymmetries among economic agents and the transaction costs involved in their activities. According to them, financial system provides means of payments that facilitates a greater number of transactions; concentrates the savings of a large number of investors; makes possible the allocation of resources to their most productive use through effective evaluation and monitoring of investment projects; improves corporate governance; and contributes to risk management. Evidence abound that there is a relationship between finance and economic growth but the direction of causality has remained the bone of contention. In summary, three schools of thought are identifiable in the extant literature: (i) supply-leading response school of thought which argues that financial development leads to economic growth pioneered by Schumpeter (1911) and confirmed by notable studies such as Levine et al. (2000), Chang and Caudill (2005), Wadud (2005) and Bittencourt (2012); (ii) demand-leading school of thought supported by studies such as Odhiambo (2004), Liang and Teng (2006), Zang and Kim (2007), Hurlin and Venet (2008), Odeniran, and Udeaja, (2010), Blanco (2009) and Waqabaca (2004), which argues that growth leads to financial development; (iii) bidirectional school of thought grounded by the studies such as Wood (1993), Akinboade (1998), Luintel and Khan (1999), Unalmis (2002), Rousseau and Vuthipadadorn (2005), Apergis et al. (2007) and Odeniran, S. O. and Udeaja, E. A. (2012) which submits that there is a bidirectional causality between financial development and economic growth.

Nigeria has an interesting history of finance sector reforms such as recapitalization, mergers and acquisition, capital controls and deflationary policies which have taken place since 2004. There are few studies on relationship between financial sector development and economic growth. Okwo et al (2012) examined the effect as well as the causal relationship between financial sector development and economic growth in Nigeria and their findings suggested that the measures of financial development showed negative relationships with economic growth. Torruam et al (2013) investigated the causal relationship between financial deepening and...
The Effect of Inflation and Financial Deepening on Output Growth: A Cointegration and ECM

Economic Growth in Nigeria and found from Granger-causality that there is unidirectional causality running from economic growth to financial deepening. This implies that developing the financial sector in Nigeria improves financial structures and ensures efficient delivery of financial services to the private sector to invest and subsequently attract more private sector participation for increase output. Adam (2011) examined how efficient the financial intermediation process has been in Nigeria’s growth performance. The study employed the 2SLS approach. The empirical results showed that financial intermediation process is sub-optimal and caused by high lending rate, high inflation rate, low per capita income, and poor branch networking. Saibu, Nwosa, and Agbeluyi, (2011) examined effects of financial development and foreign direct investment on economic growth in Nigeria. The results showed that financial development and foreign direct investment had negative effects on economic growth in Nigeria. The result also showed that financial market liquidity and not the size of the financial market matter for economic growth in Nigeria.

The remainder of this paper has the following structure: Section 2 describes the data set used. Section 3 explains the methodological framework and reports the results in section 4. Section 5 concludes the paper: it summarises the importance of the results and their implications in terms of policy.

II. Data and Model

The study used macroeconomic series that consist of yearly observations between 1970 and 2012. The study estimated the following model for Nigeria;

\[ \ln \text{RGDP}_t = \delta + \gamma_1 \ln \text{RGDP}_{t-1} + \gamma_2 \ln \text{INF}_t + \gamma_3 \ln \text{FD}_{t} + \gamma_4 \ln \text{GOV}_{t} + \gamma_5 \ln \text{TOP}_t + \mu_t \]  

\( \mu \) is error term

Definition of Variables

FD\text{CPS} - is defined as credit to private sector as share of GDP

RGDP - is real gross domestic product used to capture the real output

GOV - is total government spending

INF - is inflation rate

TOP - is trade openness measured as the ratio of the sum of export and import to GDP

The study included two macroeconomic control variables (CV): trade openness (TOP) and government expenditure (GOV) to avoid simultaneous bias (Gujarati, 2006) in the regressions. We use the natural log of the variables except for inflation, because natural logarithm of a series effectively linearizes the exponential trend (if any) in the time series data since the log function is the inverse of an exponential function (Asteriou and Price, 2007). Moreover, opting for log of the variables may prevent cumbersoness in the modelling and inference and it allows the regression coefficients to be interpreted as elasticity (Rahaman and Salahuddin, 2010). Annual data of all variables have been collected from World Bank, and International Financial Statistics (IFS) and CBN Statistical Bulletin

III. Methodological Framework

Unity Root and Cointegration Tests

In this study, the empirical investigation consists of three main steps. First, we examined the stationarity of our variables. A non-stationary time series has a different mean at different points in time, and its variance increases with the sample size (Harris and Sollis, 2003). A characteristic of non-stationarity of time series is very crucial in the sense that the linear combinations of these time series make spurious regression. In the case of spurious regression, t-values of the coefficients are highly significant, coefficient of determination (R²) is very close to one and the Durbin Watson (DW) statistic value is very low, which often lead investigators to commit a high frequency of Type 1 errors (Granger and Newbold, 1974). In that case, the results of the estimation of the coefficient became biased. Therefore it is necessary to detect the existence of stationarity or non-stationarity in the series to avoid spurious regression. For this, the unit root tests are conducted using DFGLS, and Ng-Perron. If a unit root is detected for more than one variable, we further conduct the test for cointegration to determine whether we should use Error Correction Mechanism (ECM).

Secondly, cointegration tests were conducted to see if there is a long-run or equilibrium relationship between the variables. Two popular cointegration tests, namely, the Engel-Granger (EG) test and the Johansen test are used. The EG test is contained in Engel and Granger (1987) while the Johansen test is found in Johansen (1988) and Johansen and Juselius (1990). The EG test involves testing for stationarity of the residuals. If the residuals are stationary at level, it implies that the variables under consideration are cointegrated. The EG approach could exhibit some degree of bias arising from the stationarity test of the residuals from the chosen equation. As pointed out by Idowu (2005), the EG test assumes one cointegrating vector in systems with more than two variables and it assumes arbitrary normalization of the cointegrating vector. Besides, the EG test is not very powerful and robust when compared with the Johansen cointegration test. Thus, it is necessary to complement the EG test with the Johansen test.
Short Run Dynamics within ECM Framework

Granger (1988) demonstrates that causal relations among variables can be examined within the framework of ECM, with cointegrated variables. While the short run dynamics are captured by the individual coefficients of the lagged terms, the error correction term (ECT) contains the information of long run causality. Significance of lagged explanatory variable depicts short run causality while a negative and statistical significant ECT is assumed to signify long run causality (Bannerjee and Newman, 1998). We specify the error correction term as follows;

\[ \Delta \ln \text{RGDP}_t = \delta + \gamma_1 \Delta \ln \text{RGDP}_{t-1} + \gamma_2 \Delta \ln \text{INF}_t + \gamma_3 \Delta \ln \text{FD}_t + \gamma_4 \Delta \ln \text{GOV}_t + \gamma_5 \ln \text{TOP}_t + \mu_t \]  

(4) 

\[ \mu_t = \ln \text{RGDP}_t - \delta - \gamma_1 \Delta \ln \text{RGDP}_{t-1} - \gamma_2 \Delta \ln \text{INF}_t - \gamma_3 \Delta \ln \text{RGDP}_t - \gamma_4 \Delta \ln \text{GOV}_t - \gamma_5 \ln \text{TOP}_t \]  

(5)

where \( \mu \) is the residual term and \( \gamma \) is a cointegrating coefficient. From equation (5), we can formulate a simple ECM as:

\[ \Delta \ln \text{RGDP}_t = \phi_0 + \phi_1 \Delta \text{RGDP}_{t-1} + \phi_2 \Delta \text{INF}_t + \phi_3 \Delta \text{FD}_{t-1} + \phi_4 \Delta \text{GOV}_t + \phi_5 \ln \text{TOP}_t + \Omega_{t-1} + \nu_t \]  

(6)

Specifically from the ECM expressed in equation (6), \( \phi \) captures any immediate, short term or contemporaneous effect that the explanatory variables have on the financial variable. The coefficient \( \gamma \) reflects the long-run equilibrium effect of \( \text{INF}, \text{RGDP}, \text{FD} \) and \( \text{TOP} \) on \( \text{RGDP} \) and the absolute value of \( \Omega \) decides how quickly the equilibrium is restored. We can therefore say that \( \lambda \) and \( \Omega \) are the short-run parameters while \( \phi \) is the long-run parameter.

Variance Decompositions (VDCs) and Impulse-Response Functions (IRFs)

Apart from the above battery of time series techniques, the study also generate variance decompositions (VDCs) and impulse-response functions (IRFs) to further delve into the dynamics of interaction among our variables of interest. The VDCs enable us to examine the out-of sample causality among the variables in the VAR system. It measures the percentage of the forecast error of variable that is explained by another variable. Precisely, it indicates the relative impact that one variable has on another variable. At the same time, it provides information on how a variable of interest responds to shocks or innovations in other variables. Thus, in our context, it allows us to explore the relative importance of financial development and inflation in accounting for variations in economic growth. To interpret economic implications from VDCs findings, the Sim’s (1980) innovation accounting procedure is employed. This procedure involves the decomposition of forecast error variance of each variable into components attributable to its own innovations and to shocks of other variables in the system. On the other hand, the IRFs (also known as innovation accounting in the literature) allow us to trace temporal responses of variables to its own shocks and shocks in other variables. In our context, from the IRFs we can assess the direction, magnitude and persistent of economic growth responses to innovations in the financial development and inflation. Finally, following Narayan and Smyth (2005), we test for parameter stability of the long-run parameters together with the short-run movements for the equations. (Abd.Majid, 2007).

IV. Empirical Results and Discussion

Unit Root Test

In order to examine the integrating level of variables, standard tests like DF-GLS, and Ng-Perron were employed. Mostly in the literature to find out the order of integration ADF (Dicky& Fuller, 1979) and PP (Philip &Perron, 1988) tests have been used extensively. Due to their poor size and power properties, both tests are not reliable for small sample data set (Dejong et al, 1992 and Harris and Sollis, 2003). These tests seem to over-reject the null hypotheses when it is true and accept it when it is false. While newly proposed tests such as Dicky-Fuller generalized least square (DF-GLS) de-trending test developed by Elliot et al. (1996) and Ng-Perron test following Ng-Perron (2001) seem to solve this arising problem.

The unit root results reported in Table 1 showed that all the series, except inflation, are non-stationary at level but become stationary after taking their first difference i.e. I(1). Thus we apply the Engel - Granger cointegration test to long run relationship between the variables. Following the modeling approach described earlier, we determine the appropriate lag length and conducted the cointegration test.

Table 2 reports the optimal lag length of one out of a maximum of 4 lag lengths as selected by the five criterions. The EG test presented in table 3 showed that the series in our model is stationary at level under Augmented Dickey-Fuller (ADF), Philip-Perron (PP) and KPSS unit root tests. Therefore, the Engel - Granger cointegration test suggests that the variables are cointegrated.

Note: P-values in bracket (); The null hypothesis is that the series is stationary. The critical values for 1%, 5%, and 10% levels are, respectively: 0.7396, 0.4639 and 0.3470

To complement the EG test, the Johansen test was conducted and reported in Tables 4. Table 4 provided the results from the application of Johansen cointegration test among the data set. The results are based on the assumptions of linear deterministic trend and lag interval in first difference of 1 to 1. Trace test rejected the null hypothesis of no cointegration at both 10 percent significance level while maximum eigenvalue do not reject the null hypothesis of no cointegration at the same level of significance.

Based on the existence of cointegration relationship among the variables, we therefore estimate the long-run relationships using the Stock-Watson’s dynamic ordinary least squares (DOLS) model. The presence of leads and lags for different variables eliminates the bias of simultaneity within a sample and DOLS estimates
The Effect of Inflation and Financial Deepening on Output Growth: A Cointegration and ECM

and provide better approach to normal distribution. DOLS model with dependent variable \( y \), and independent variable \( x \), is specified as below:

\[
y_t = \phi_0 + \phi x_t + \sum_{j=-m}^{n} d \Delta x_{ij} + \epsilon_t
\]

Where \( n \) and \( m \) show lag and lead length, and \( \phi \) indicates the long run effect of a change in \( x \) on \( y \). The reason why lag and lead terms are included in DOLS model is that they have the role to make its stochastic error term independent of all past innovations in stochastic repressors (Baba et al., 1992).

Note: Leads and lags were set to 1 and 2 respectively for DOLS estimators. ***, ** and * shows statistical significance at 1%, 5% and 10% level.

Panel A of Table 5, brings out the precise nature of the long-run relationship among the variables with Output as the dependent variable, the following inferences can be drawn: first, the coefficient of inflation is found to be positive and statistically significant indicating an increase in inflation in the long-run raises real output during the study period. Second, the long-run coefficient of financial development is found also to be positive but not statistically significant supporting the premise that financial intermediation promotes economic growth. Third, the estimated long-run coefficient of trade openness is negative and significant indicating that trade liberalization has a deleterious effect on economic growth. This might be due to the fact that Nigeria is a primary product producer and exporter. Finally, the result shows that government spending is not neutral to economic growth; rise in government expenditure will enhance output growth. The results from Panel B and Panel C give an indication that inflation effect on growth is independent of financial development while the financial development effect on growth is dependent on inflation.

The long run association established implies causality but it does not reveal the directions of causation amongst in the model. Thus we proceed in our analysis by reporting in Table 6 the multivariate causalities among the economic growth (RGDP), inflation (INF), financial development (FD), trade openness (TOP) and government spending (GOV).

p-value in bracket ();
The ECMs of all the models confirm a long run relationship among the variables. Specifically from our main model, this implies that any deviations from the long-run equilibrium relationships in the Nigerian economy are mainly caused by changes in real GDP. The P-value of the error correction term coefficient shows that it is statistically significant at a 1% level, thus suggesting that output growth adjust to the explanatory variables and the coefficient of the lagged ECM is equal to -0.5214 for short run model implying that the deviation from the long-term equilibrium is corrected by about 53 percent over the following year. This means that the adjustment takes place very quickly.

We also found no evidence of short run causality between RGDP and INF; and there is existence of short run interaction between RGDP and FD i.e., a bi-directional causality between the variables. Many empirical studies (such as Guiso, Sapienza and Zingales, 2004; Levine, 2006; Demirguc-Kurt and Levine, 2001) have supported the view that an improved or developed financial system is able to promote high economic expansion through technological changes, product and service innovation, which in turn will create high demand on the financial services and as the financial institutions effectively respond to these demand, then these changes will stimulate a higher economic achievement. Both financial and economic development are therefore positively interdependent and their relationships could then lead to bi-directional causality. However, the result of our main model reveals a negative interdependent between economic growth and financial development, which is in agreement with other findings such as Akinlo and Egbede (2010), Saibu, Nwosa, and Aghbeluyi, (2011), Adusei (2012) and Okwo et al (2012).

The study further explored the dynamic interaction between financial development and economic growth by testing the variance decompositions (VDCs) and impulse-response functions (IRFs) of the model. The results of VDCs is reported in Table 7 and it provides detailed information on the relative strength of the financial depth, share of investment and inflation in explaining the changes in the economic growth. From the VDCs and IRFs results, we are also able to capture the relative importance of various shocks and their influences on the economic growth. The VDCs and IRFs are simulated by orthogonalizing the innovations in the vector autoregression (VAR) equations using the so-called Cholesky decomposition suggested by Sims (1980) with the orderings of the variables: lnRGDP, lnFD, INF, lnGOV and lnTOP. Based on VDCs results for the horizon of 1 to 12 periods, we find that the variations in the economic growth in Nigeria respond more to shocks in trade openness and next government spending. The variations in the economic growth in the country, however, rely more on its own innovations. For instance in 10th period, the result indicates that about 96 percent portion of economic growth is explained by its own innovative shocks while innovative shocks of financial development, inflation, government expenditures and trade openness to economic growth is by 1.01 percent, 0.77 percent, 1.99 percent and 0.41 percent respectively.

The effect of financial development as measured by share of credit to private sector in GDP is low in the long run and negative in the short run as demonstrated (see Tables 5 and 6). This finding may be explained in line with the observations of Shen and Lee (2006) that provided evidence that only stock market development has positive effects on growth and that banking development has an unfavorable, if not negative, effect on growth. More so, Saci et al. (2009) following Levine et al. (2000), Rousseau and Wachtel (2000); Beck and Levine (2002) and Yao (2006) found that while the stock market variables in their model are positively and significantly related to growth, the standard banking sector variables (credit to the private sector and liquid liabilities) have negative effects on growth.

To complement our analysis on the VDCs, the study further generated the impulse response functions (IRFs). As reported in Figure 1, the overall results seem to be very much consistent with our earlier findings. Economic growth seems to have immediate response to shocks in the financial depth and share of investment. This further implies that any policies pertaining to the price stability, investment and financial development should at least be noted by the government in order to speed up their economic growth.
Finally, we have examined the stability of the long-run parameters together with the short-run movements for the equations. For test, the study relied on cumulative sum (CUSUM) and cumulative sum squares (CUSUMSQ) tests that were proposed by Borensztein, et al. (1998). The same procedure has been utilized by Pesaran and Pesaran (1997), Suleiman (2005) and Mohsen et al (2002) to test the stability of the long-run coefficients. The tests applied to the residuals of the ECM model.
Figures 2 and 3 plot the CUSUM and CUSUM of squares statistics for Equation (6). It can be seen from both Figures that the plot of CUSUM and CUSUMSQ stay within the critical 5% bounds that confirm the long-run relationships between variables and also shows the stability of coefficient. Hence the model adopted in this study seems to be good enough and robust in estimating the short- and long-run relationships between financial development and economic growth.

V. Summary, Conclusions and Policy Implications

This study aimed at empirically exploring the triangle of relationships – finance-inflation-growth with the broader data that have been used in the recent empirical literature on growth and to see whether a direct effect of inflation on growth can be identified as well as an indirect effect through financial sector development. It attempts to investigate the finance-inflation-growth nexus using multivariate causality tests within a vector error correction model (VECM) and also seeks to explore the relative strength of the variables in affecting economic growth using the variance decompositions (VDCs) and the impulse-response functions (IRFs) based on the structural vector autoregression (VAR) framework. After studying the time-series properties of these variables for stationarity and cointegration, the study employed dynamic ordinary least square (DOLS) to estimate the long run relationship and investigate the causal relations among variables within the framework of ECM. We found that both Engel - Granger and Johansen cointegration test suggest that the variables are cointegrated. Based on the existence of cointegration relationship among the variables, we therefore estimate the long-run relationships using the Stock-Watson’s dynamic ordinary least squares (DOLS) model. The results of
DOLS model give an indication that inflation effect on growth is independent of financial development while the financial development effect on growth is dependent of inflation. Furthermore, we also found no evidence of short run causality between RGDP and INF; and there is existence of short run interaction between RGDP and FD that is a bi-directional causality between the variables. Variance decompositions (VDCs) results revealed the variations in the economic growth in Nigeria respond more to shocks in trade openness and next government spending, however, the variations in the economic growth rely more on its own innovations. The policy implication of this finding is for policy makers to develop strategy that will holistically reform the financial system and enhance stock market development along side with banking financial institutions. Finally, since financial development effect on growth is dependent of inflation, policy that will ensure price stability will promote output further.
