Abstract: In this paper we have discussed about the circular motion and its applications. The basic concept of dynamics and derivation of circular motion is derived. The application problem such as satellite in a circular orbit, moving car are solved by using derivation of circular motion.  

Keywords: centripetal force, centrifugal force, clothoid, conical pendulum, uniform magnetic field,

I. Introduction

In physics circular motion is a movement of an object along the circumference of a circle or rotation along a circular path. It can be uniform, with constant angular rate of rotation and constant speed, or non-uniform with a changing rate of rotation. The rotation around a fixed axis of a three-dimensional body involves circular motion of its parts. The equations of motion describe the movement of the center of mass of a body.

Examples of circular motion include: an artificial satellite orbiting the Earth at a constant height, a stone which is tied to a rope and is being swung in circles, a car turning through a curve in a race track, an electron moving perpendicular to a uniform magnetic field, and a gear turning inside a mechanism.

Since the object's velocity vector is constantly changing direction, the moving object is undergoing acceleration by a centripetal force in the direction of the center of rotation. Without this acceleration, the object would move in a straight line, according to Newton's laws of motion.

Principle of circular motion

If the direction of the acting force is in the same direction of motion, The velocity of the moving object increases, the direction of motion does not change.

Example: when the motorcyclist pumps more fuel, the motorbike is acted upon by a force in the same direction of motion and accelerates or increases velocity.

If the direction of the acting force is opposite to the direction of motion, The velocity of the moving object decreases. The direction of motion does not change.

Example: When the motorcyclist applies the brakes, the motorbike is acted upon by a force opposite to the direction of motion and decelerates or decreases velocity.

APPLICATIONS OF UNIFORM CIRCULAR MOTION

BANKING OF ROADS

While riding a bicycle and taking a sharp turn, you may have felt that something is trying to throw you away from your path.

You tend to be thrown out because enough centripetal force has not been provided to keep you in the circular path. Some force is provided by the friction between the tyres and the road, but that may not be sufficient. When you slow down, the needed centripetal force decreases and you manage to complete this turn.

Consider a car of mass m, travelling with speed v on a curved section of a highway. To keep the car moving uniformly on the circular path, a force must act on it directed towards the centre of the circle and its magnitude must be equal to \( \frac{m v^2}{r} \).

If the road is levelled, the force of friction between the road and the tyres provides the necessary centripetal force to keep the car in circular path. This causes a lot of wear and tear in the tyre and may not be enough to give it a safe turn. The roads at curves are, therefore, banked, where banking means the raising of the outer edge of the road above the level of the inner edge.

ROLLER COASTERS AND CENTRIPETAL FORCE

People ride roller coasters, of course, for the thrill they experience, but that thrill has more to do with centripetal force than with speed. By the late twentieth century, roller coasters capable of speeds above 90 MPH (144 km/h) began to appear in amusement parks around America; but prior to that time, the actual speeds of a roller coaster were not particularly impressive. Seldom, if ever, did they exceed that of a car moving down the highway. On the other hand, the acceleration and centripetal force generated on a roller coaster are high, conveying a sense of weightlessness (and sometimes the opposite of weightlessness) that is memorable indeed.

Few parts of a roller coaster ride are straight and flat—usually just those segments that mark the end of one ride and the beginning of another. The rest of the track is generally composed of dips and hills, banked turns, and in some cases, clothoid loops. The latter refers to a geometric shape known as a clothoid, rather like a teardrop upside-down.

Because of its shape, the clothoid has a much smaller radius at the top than at the bottom—a key factor in the operation of the roller coaster ride through these loops. In days past, roller-coaster designers used perfectly circular loops, which allowed cars to enter them at speeds that were too high, built too much force and resulted in injuries for riders. Eventually, engineers recognized the clothoid as a means of providing a safe, fun ride.

As you move into the clothoid loop, then up, then over, and down, you are constantly changing position. Speed, too, is changing. On the way up the loop, the roller coaster slows due to a decrease in kinetic energy, or the energy that an object possesses by virtue of its movement. At the top of the loop, the roller coaster has gained a great deal of potential energy, or the energy an object possesses by virtue of its position, and its kinetic energy is at zero. But once it starts going down the other side, kinetic energy—and with it speed—increases rapidly once again.

Throughout the ride, you experience two forces, gravity, or weight, and the force (due to motion) of the roller coaster itself, known as normal force. Like kinetic and potential energy—which rise and fall correspondingly with dips and hills—normal force and gravitational force are locked in a sort of "competition" throughout the roller-coaster ride. For the coaster to have its proper effect, normal force must exceed that of gravity in most places.

The increase in normal force on a roller-coaster ride can be attributed to acceleration and centripetal motion, which cause you to experience something other than gravity. Hence, at the top of a loop, you feel lighter than normal, and at the bottom, heavier. In fact, there has been no real change in your weight: it is, like the idea of "centrifugal force" discussed earlier, a matter of perception.

CONICAL PENDULUM

A conical pendulum consists of a weight (or bob) fixed on the end of a string or rod suspended from a pivot. Its construction is similar to an ordinary pendulum; however, instead of swinging back and forth, the bob of a conical pendulum moves at a constant speed in a circle with the string (or rod) tracing out a cone.
Let \( OP = L \) be the string, \( O \) being fixed and the particle being attached at \( P \). The particle describes a circle of radius \( r \), \( h \) being the depth of the circle below \( O \). Let \( \theta \) be the inclination of the string with the vertical \( ON \). Then,

\[
\sin \theta = \frac{r}{l}
\]

\[
l \sin \theta = r
\]

\[
l \cos \theta = \frac{h}{l}
\]

\[
h = l \cos \theta
\]

\[
r = l \sin \theta
\]

If \( w(=\theta) \) be the angular velocity then the central acceleration \( w^2r \) towards \( N \). Now the forces acting on \( P \) are:
- Its weight \( mg \) downwards,
- The tension \( T \) in the direction \( OP \) of the string

The equations of motion for \( P \) are:

\[
T \cos \Theta - mg = 0 \quad \rightarrow \quad 1
\]

\[
T \cos \theta = mg
\]

\[
T = \frac{mg}{\cos \theta}
\]

Since there is no motion for \( P \) in the vertical direction:

\[
rw^2 = T \sin \theta \quad \rightarrow \quad 2
\]

Eliminating \( T \) between 1 and 2:

\[
rw^2 = \frac{mg}{\cos \theta} \sin \theta
\]

\[
w^2 = \frac{mg}{mr \cos \theta}
\]

\[
w^2 = \frac{g \sin \theta}{r \cos \theta}
\]

\[
w^2 = \frac{g r / l}{r h / l}
\]

\[
w^2 = \frac{g}{l - h}
\]

\[
w = \sqrt{\frac{g}{l - h}}
\]

Thus the angular velocity varies inversely as the square root of the depth of \( P \) below \( O \).

Time of one complete revolution is:

\[
\frac{2\pi}{w} = \frac{2\pi}{\sqrt{\frac{g}{l - h}}}
\]

If the particle makes \( n \) revolutions per second, the angular velocity \( w = 2\pi nh \) radian/sec.

From 3,

\[
w^2 = \frac{\theta}{r} = \frac{\sin \theta}{\cos \theta}
\]

(by 3)

\[
r 4\pi^2 n^2 = \frac{g}{\cos \theta} \sin \theta
\]

\[
\theta \neq 0,
\]

\[
\cos \theta = \frac{g \sin \theta}{l \sin \theta 4\pi^2 n}
\]
\[ \cos \theta = -\frac{g}{4\pi^2 n^2 l} \]

For \( \theta \) to be real the conditions is,
\[ 4\pi^2 n^2 l > g \]

Tension \( T = \frac{mg}{\cos \theta} \)
\[ T = mg \frac{4\pi^2 n^2 l}{g} \]

Hence proved

**MASS PERFORMING VERTICAL CIRCULAR MOTION UNDER GRAVITY**

Consider a mass \( m \) performing circular motion under gravity, the circle with radius \( r \)

The centripetal force on the mass varies at different position on the circle

Top \( mg + T = \frac{mv^2}{r} \)

Middle \( T = \frac{mv^2}{r} \)

Bottom \( T - mg = \frac{mv^2}{r} \)

String at an angle \( \theta \) to the vertical

\[ mg \cos \theta + T = \frac{mv^2}{r} \]

Hence proved

**II. Problems**

**PROBLEM: 1**

In a conical pendulum making \( n \) revolution per second, the length \( l \) of the string in diminished by a small length \( x \) show that the increase in the number of revolution per second is approximately \( \frac{n}{2l} \) the inclination of the string to the vertical and the tension remaining the same.

**Solution:**

We know that, the tension \( T \) In a conical pendulum making \( n \) revolution per second is given by \( T = 4\pi^2 n^2 l m \)

Assuming \( T, m, 4\pi^2 \) as constant taking logarithms,

\[ \log T = \log 4\pi^2 + 2\log n + \log l \]

Taking differentials,

\[ 0 = 0 + 2 \frac{dn}{n} + \frac{dl}{l} \]

\[ - \frac{dl}{l} = 2 \frac{dn}{n} \]

\[ - \frac{2l}{2l} = \frac{dn}{n} - \frac{dl}{l} \]

\[ dn = -n \frac{dl}{2l} \]

\[ dl = -x \]
\[ dn = -\frac{n(-x)}{2l} \]
\[ dn = \frac{nx}{2l} \]

**RESULT:**
The increase in the number of revolution per second is approximately \( \frac{nx}{2l} \)
The inclination of the string to vertical and the tension remaining the same

**PROBLEM: 2**
A 20g mass move as a conical pendulum with string length 8x and speed v if the radius of the circular motion is 5x find,

i. The string tension (assuming \( g=10\text{ms}^{-1} \) )
ii. V in terms of x .g

**Solution:**

i. \( l = 8x \)
\( m = 20\text{g}= 0.02\text{ kg} \)
\( r = 5x \)
\( g = 10\text{ ms}^{-1} \)
\( \cos\theta = \frac{5}{8} \)
\( \theta=51.3^\circ \)

\[ T \sin\theta = mg \quad \text{(by conical pendulum)} \]
\[ T = \frac{mg}{\sin\theta} \]
\[ T = \frac{0.02 \times 10}{0.7804} \]
\[ T=0.2563 \]

The string tension T is 0.26 N

ii. Resolution horizontally

\[ T \cos\theta = \frac{mv^2}{r} \]
Substituting for T, from \( T = \frac{mg}{\sin\theta} \) above,

\[ \frac{mg \cos\theta}{\sin\theta} = \frac{mv^2}{r} \]

\[ \frac{gr}{\tan\theta} = v^2 \]

\[ V=\sqrt{\frac{gr}{\tan\theta}} \]

Substituting for \( r = 5x, \ \theta=51.3^\circ \)

\[ V=\sqrt{\frac{5gx}{\tan(51.3^\circ)}} \]
\[ V=\sqrt{\frac{5gx}{1.24820}} \]
\[ V=\frac{5gx}{4.0057} \]
\[ V=\sqrt{4gx} \]
\[ V=2\sqrt{gx} \]

Velocity v in terms of gx is \( 2\sqrt{gx} \)

**RESULT:**
The string tension T is 0.26 N

Velocity v in terms of gx is \( 2\sqrt{gx} \)

**PROBLEM: 3**
A 50g mass suspended at the end of a light inextensible string performs vertical motions of radius 2m if the mass has a speed of \( 5\text{ms}^{-1} \) when the string makes an angle of 30° with the vertical. What is the tension?

**Solution:**

\( m= 50\text{g} = 0.05\text{ kg} \)
\( v= 5\text{ ms}^{-1} \)
\( \theta=30^\circ \)
\( r = 2m \)
\( g = 10\text{ ms}^{-1} \)
The centripetal force is the sum of the tension in the string and the component of the weight along the string.

\[ mg \cos \theta + T = \frac{mv^2}{r} \]

\[ T = \frac{mv^2}{r} - mg \cos \theta \]

\[ T = \left(0.05\right)^2 - \left(0.05\right) \left(10\right) \cos30^\circ \]

\[ T = \frac{\left(0.05\right)^2}{2} - \left(0.05\right) \left(10\right) 0.8660254038 \]

\[ T = 2.5 - 4.330127019 \]

\[ T = 0.625 - 0.4330127019 \]

\[ T = 0.192 \]

\[ T = 0.192 \]

RESULT:
The tension of string is 0.2 N

PROBLEM 4:
A 30g mass suspended at the end of light inextensible string performs vertical motions of radius 2m if the mass has a speed of 5m/s when the string makes an angle of 45° with the vertical what is the tension?

**Solution:**

\[ m= 30g = 0.03kg \]

\[ v=5m/s \]

\[ \theta = 45^\circ \]

\[ r = 2m \]

\[ g=10m/s^2 \]

The centripetal force is the sum of the tension in the string and the component of the weight along the string.

\[ mg \cos \theta + T = \frac{mv^2}{r} \]

\[ T = \frac{mv^2}{r} - mg \cos \theta \]

\[ T = \left(0.03\right)^2 - \left(0.03\right) \left(10\right) \cos45^\circ \]

\[ T = \frac{\left(0.03\right)^2}{2} - \left(0.03\right) \left(10\right) 0.7071067812 \]

\[ T = 0.2121318 \]

\[ T = 0.1628682 \]

\[ T = 0.163N \]

RESULT:
The tension of string 0.163 N

APPLICATION PROBLEM

**PROBLEM 5**

A Space shuttle moving at 1000 m/s in a circular orbit around a distant moon. If the radius of the circle followed by the satellite is 1000km find?

i. The acceleration of the space shuttle.

ii. The time for the space shuttle to complete one full orbit of the moon in minutes

**Solution:**

i. \[ a \] is acceleration, \[ v \] speed and \[ r \] orbit radius

\[ a = \frac{v^2}{r} \]

Substituting for \[ v = 1000 \text{ m/s} \]

\[ r = 1000 \text{ km} \left(10^6\right) \]

\[ a = \frac{\left(1000\right) \left(1000\right)}{1000000} \]
a=1

Acceleration of the space shuttle is $1 \text{m} \cdot \text{s}^{-1}$

ii. distance travelled by space shuttle in one orbit = circumference of orbit circle

Time for one orbit = $\frac{\text{distance travelled in one orbit}}{\text{speed}}$

$= \frac{2\pi \times 10^6}{2 \times 10^3} = 2 \pi \times 10^3$

$= 6285 \text{sec}$

$= 104.76 \text{ min}$

RESULT:

Acceleration of the space shuttle is $1 \text{m} \cdot \text{s}^{-1}$

Time for one orbit is $104.76 \text{ min}$

PROBLEM: 6

A 900kg truck moving at 20m/s takes a turn around a circle with a radius of 25.0m determine the acceleration and the net forces acting upon the car?

Solution:

$m = 900 \text{ kg}$

$R = 25.0 \text{ m}$

$V = 20.00 \text{ m/s}$

Acceleration = ?

$f_{\text{net}} = ?$

To determine the acceleration of the truck, use the equation $a = \frac{v^2}{R}$

$a = \frac{(20.00)^2}{25.0} = 16 \text{ m/s}^2$

To determine the net force acting upon the truck, use the equation $F_{\text{net}} = ma$

$f_{\text{net}} = (900) (16 \text{ m/s}^2)$

$= 900 \times 16$

$= 14400 \text{ N}$

Hence proved

PROBLEM: 7

A 95kg halfback makes a turn on the football field. The halfback sweeps out a path that is a portion of a circle with a radius of 12meters. The halfback makes a quarter of a turn around the circle in 2.1seconds. Determine the speed, acceleration and net force acting upon the halfback?

Solution:

$m = 95.0 \text{ kg}$

$R = 12.0 \text{ m}$

$V = ?$

$a = ?$

$f_{\text{net}} = ?$

Travelled $1/4^{th}$ of the circumference in 2.1s

To determine the speed of the halfback use the equation $v = \frac{d}{t}$ where the $d$ is $1/4^{th}$ of the circumference and the time is 2.1s The solution is,

$V = \frac{0.25 \times 2 \pi \times R}{t}$

$V = \frac{2 \pi \times 12 \times 0.25}{2.1}$
To determine the acceleration of the half back, use the equation \( a = \frac{v^2}{r} \)

\[
\begin{align*}
v &= 18.84 \text{ m/s} \\
V &= 2.18s \\
V &= 8.97 \text{ m/s}
\end{align*}
\]

To determine the acceleration of the half back, use the equation \( a = \frac{(8.97 \text{ m/s})^2}{12.0m} \)

\[
a = \frac{0.05 \text{ m/s}^2}{12.0m}
\]

\[
a = 6.71 \text{ m/s}^2
\]

To determine the net force acting upon the half back, use the equation \( f_{\text{net}} = m \times a \)

The solution is,

\[
\begin{align*}
f_{\text{net}} &= (95.0 \text{ kg}) \times (6.71 \text{ m/s}^2) \\
f_{\text{net}} &= 637 \text{ N}
\end{align*}
\]

**RESULT:**

- The speed \( v=8.97 \text{ m/s} \)
- Acceleration = 6.71 m/s²
- Net force = 637 N
