Abstract: Harmonious colouring is a proper vertex colouring such that no two edges share the same colour pair. The harmonious Chromatic number \( \chi_h(G) \) of a graph is the least number of colours in such a colouring.

In this paper we give some new properties of harmonious colouring graphs and its applications.

Keywords: Harmonious Colouring, Harmonious chromatic Number, Upper bound, Lower bound.

I. Introduction

Graph Colouring

It is more than 200 years old. It has a many practical applications like computer science, telecommunications, operation research, designs of experiments etc. It is a special case of graph labeling.

Harmonious colouring

It is a recent growing topic in the last three decades. Harmonious colouring number is used in the different families of graph such as trees, cycles, complete bipartite graphs etc. In this topic more than fifty papers are published. A harmonious Colouring of a simple graph \( G \) is a proper vertex colouring such that each pair of colours appears together on at most one edge. The harmonious Chromatic number \( \chi_h(G) \) of a graph is the least number of colours in such a colouring, where \( G \) is a finite undirected graph with no loops and multiple edges.

In 1989, Donald G. Beare[3] he gives information about the growth rate of the harmonious Chromatic number of a family of regular graphs as a function of the number of vertices when the valency (or) the diameter is fixed and families of graphs where the harmonious coloring is minimal. In 1999, Keith Edwards [12] he define the relation between harmonious chromatic number and least positive integer.

In 2006, K. Thilagavathi and J.V. Vivin[10] gives the result of harmonious chromatic number of line graph of central graph of \( c_n, k_n, k_{1,n}, k_{n,n} \) and its line graphs denoted by \( L[C(c_n)], L[C(k_n)], L[C(k_{1,n})], L[C(k_{n,n})] \) respectively.

II. Definitions

1. Chromatic Colouring and Chromatic Number

Let \( G(V,E) \) be a graph and \( \phi : V \rightarrow N \) a labelling of the vertices. \( \phi \) is a proper colouring if for every \( u,v \in V \) with \( (u,v) \in E \) then \( \phi(u) \neq \phi(v) \), in other words neighbouring vertices should not be assigned the same colour. The chromatic number denoted by \( \chi(G) \).

2. Achromatic Colouring and Achromatic Number

The achromatic colouring of a graph is a proper vertex colouring such that each pair of colour classes is adjacent by at least one edge. The largest possible number of colours in an achromatic colouring of a graph \( G \) is called the and it is denoted by \( \chi_a(G) \).

www.iosrjournals.org 13 | Page
3. Pseudo Achromatic Number
The pseudo achromatic number $\alpha(G)$ is the maximum $k$ for which there exists a complete colouring of $G$. If the colouring is required also to be proper, then such a maximum is known as the achromatic number and it will be denoted here by $\chi_a(G)$.

4. Line Distinguishing Colouring
Let $G(V,E)$ be a graph. A colouring $\phi : V \rightarrow N$ of the vertices is a line distinguishing colouring iff for every edge $(u, v) \in E$ the edge colour $(\phi(u), \phi(v))$ is unique, i.e., it appears at most once.

5. Harmonious Colouring and Harmonious Chromatic Number
A harmonious colouring of a graph $G(V,E)$ is a line-distinguishing colouring which is also proper. The harmonious chromatic number of $G$ (denoted by $\chi_h(G)$) is the smallest number $k$ such that there exists a harmonious colouring of $G$ of $k$ colors.

6. Exact coloring
An exact coloring of a graph $G(V,E)$ is a coloring which is harmonious and complete at the same time.

7. Central graph
Let $G$ be a finite undirected graph with no loops and multiple edges. The central graph $C(G)$ of a graph is obtained by subdividing each edge of $G$ exactly once and joining all the non adjacent vertices of $G$.

8. (2,n) Barbell graph
The $(2,n)$-Barbell graph is the simple graph obtained by connecting two copies of a complete graph $K_n$ by a bridge and it is denoted by $B(K_n,K_n)$. From the observation of barbell graph definition, we define the following definition:

9. (3,n) Barbell graph
The $(3,n)$-Barbell graph is the simple graph obtained by connecting three copies of a complete graph $K_n$ by a bridge and it is denoted by $B(K_n,K_n,K_n)$.

10. (N,n) Barbell graph
In general the $(N,n)$-Barbell graph is the simple graph obtained by connecting $N$ copies of a complete graph $K_n$ by a bridge and it is denoted by $B(K_n,K_n,K_n,\ldots,N$ times $K_n)$.

Some of the most important results on harmonious and achromatic colouring graphs, that appeared in the literature survey. For studying these particular kinds of colouring by presenting several potential applications[17].

IV. Observation

Theorem 1:
The pseudo achromatic number \( \alpha (G) \) is the maximum \( k \) for which there exists a complete colouring of \( G \). If the colouring is required also to be proper, then such a maximum is known as the achromatic number and it will be denoted here by \( \chi_a(G) \). Clearly \( \chi(G) \leq \chi_a(G) \leq \alpha(G) \), where \( \chi(G) \) denotes the chromatic number of \( G \).

Theorem 2:

Exhibiting an explicit colouring and showing a general upper bound is follows that, if \( q = 2^\beta \), for some \( \beta \in \mathbb{N} \), and \( n = q^2 + q + 1 \), then \( q^3 + q \leq \alpha(n) \leq q^3 + \frac{1}{2} q^2 + 1 \). Besides those implied by Bouchet’s theorem, very few exact values for \( \chi_a(n) \) are known.

Corollary 1:

We were able to calculate exactly \( \alpha(n) \) in the following family, if \( q = 2^\beta \), for some \( \beta \in \mathbb{N} \), and \( n = q^2 + 2q + 2 \), then \( \alpha(n) = q(n+1) = q^3 + 2q^2 + 3q \).

Theorem 3:

Classes of graph that can be decomposed into bounded sized components by removing a small proportion of the vertices, then such graphs of bounded degree the harmonious chromatic number is close to the lower bound \( (2m)^{1/2} \) where \( m \) is the number of edges.

Theorem 4:

Let \( G \) be a graph and \( H \) be a subgraph of \( G \). Then \( \chi_a(G) \geq \chi_a(H) \).

Theorem 5:

Let \( G(V,E) \) be a disconnected graph and \( k \) an integer number. The problem of determining whether \( \chi_h(G) \geq k \) is NP-complete.

Theorem 6:

If \( G(V,E) \) is a graph with \( |E| = m \) and \( Q(m) \) are defined as above then \( \chi_h(G) \geq Q(m) \) and \( \chi_a(G) \leq q(m) \), where \( Q(m) \) be the smallest positive integer \( k \) such that \( m \leq \binom{k}{2} \) and \( q(m) \) be the greatest integer number \( l \) such that \( m \geq \binom{l}{2} \).

Theorem 7:

Let \( G(V,E) \) be a graph and \( \chi(G) \) be its chromatic number, then \( \chi(G) \leq \chi_a(G) \).

Theorem 8:

For any complete graph \( K_n, \chi_h[B(K_n,K_n)] = 2n-1, n \geq 2 \). Here \( B(K_n,K_n) \) Satisfies the following properties: (i) The number of vertices in \( B(K_n,K_n) \) is \( 2n \). (ii) The number of edges in \( B(K_n,K_n) \) is \( n^2 - n + 1 \). (iii) The maximum degree in \( B(K_n,K_n) \) is \( n \). (iv) The minimum degree in \( B(K_n,K_n) \) is \( n-1 \).

In this paper, we improved the result for 3 copies of barbell graph by our definition (9) it has given below:

Theorem 9:

For any complete graph \( K_n, \chi_h[B(K_n,K_n,K_n)] = 3n-2, n \geq 2 \).

Proof:

Step 1: Let \( G = B(K_n,K_n,K_n) \) be the Barbell graph.

Step 2: By the definition, \( (3,n) \) Barbell graph is obtained by connecting three copies of complete graph \( K_n \) by a bridge. Let \( V = \{ v_1, v_2, v_3, \ldots, v_n \} \) be the vertex set of \( K_n \). \( W = \{ w_1, w_2, w_3, \ldots, w_n \} \) be the vertex set of \( K_n \) and \( X = \{ x_1, x_2, x_3, \ldots, x_n \} \) be the vertex set of \( K_n \).

Step 3: Now the colouring assignments are as follows. Since \( K_n \) contains exactly \( n \) vertices \( (n \geq 2) \) which are mutually adjacent to each other, we should colour all the \( n \) vertices of \( K_n \) with \( n \) different colours \( B_i \), where
On A Harmonious Colouring Graphs And Its Applications

On A Harmonious Colouring Graphs And Its Applications

i=1,2….n. For colouring ‘K^2’, we should use ‘n’ different colours C_i apart from B_i and any one colour from B_i, 1≤ i ≤n.

Step4: Similarly colour ‘K^3’, we should use ‘n’ different colours apart from C_i and any one colour from C_i, 1≤ i ≤n.

Step5: Thus the number of colours required = n+(n-1)+(n-1) = 3n-2.

Example 1

**Graph theory:**

It has many applications like, radio navigation, and image compression. In computer science, graphs are used to represent networks of communication, data organization, computational devices, the flow of computation, etc.

**Example 2**

The link structure of a website could be represented by a directed graph. The vertices are the web pages available at the website and a directed edge from page A to page B exists if and only if A contains a link to B. A similar approach can be taken to problems in travel, biology, computer chip design, and many other fields. The development of algorithms to handle graphs is therefore of major interest in computer science.

**Graph colouring:**

The problem of colouring a graph has number of applications. Some of them are scheduling, bandwidth allocation, pattern matching and puzzle Sudoku. Few examples are given as follows:

**List colouring:**

In the list colouring problem each vertex v has a list of available colours, and we have to find a colouring where the colour of each vertex is taken from its list of available colors. List colouring can be used to model situations where a job can be processed only in certain time slots, or if it can be processed only by certain machines.

**Multi colouring:**

A natural generalization of is to consider jobs that require more than one time slots. In the multi colouring problem each vertex v has a demand x(v), and we have to assign a set of x(v) colors to each vertex v such that neighbours receive disjoint sets of colors. Multi colouring can be used to model the scheduling of jobs with different time requirements: the set of colours assigned to vertex v corresponds to the x(v) time slots when we work on the job.

**Minimum sum colouring:**

In scheduling theory is to minimize the sum of completion times of the jobs, which is the same as minimizing the average completion time. The corresponding colouring problem is minimum sum colouring. we are looking for a colouring of the conflict graph such that the sum of the colours assigned to the vertices is minimal. Apart from trees, partial k-trees, and edges of trees, minimum sum colouring is NP-hard on most classes of graphs.

**Harmonious Colouring:**

It has potential applications in communication networks. For example transportation networks, computer networks. Application in radio navigation systems (ie) aviation guiding systems in bad weather.
On A Harmonious Colouring Graphs And Its Applications

conditions or in case of invisibility on ground objects. The airway network system is considering an optimal harmonious colouring on the graph where nodes represent the positions of the radio beacons and edges represent the airways. Also many applications like it has to be used in data compression (design of minimal hash functions) and clustering.

VI. Conclusion:

In this paper we discussed about the Properties of harmonious chromatic number of graphs. These types of colourings presenting several applications. Also we discussed about the harmonious chromatic number of barbell graphs with n copies.
