Abstract: Concrete is a mixture of cement, fine aggregate, coarse aggregate and water. Concrete plays a vital role in the development of infrastructure Viz., buildings, industrial structures, bridges and highways etc. leading to utilization of large quantity of concrete. On the other side, cost of concrete is attributed to the cost of its ingredients which is scarce and expensive, this leading to usage of economically alternative materials in its production. This requirement is drawn the attention of investigators to explore new replacements of ingredients of concrete. The present technical report focuses on investigating characteristics of concrete with partial replacement of cement with Ground Granulated Blast furnace Slag (GGBS). The topic deals with the usage of GGBS and advantages as well as disadvantages in using it in concrete. This usage of GGBS serves as replacement to already depleting conventional building materials and the recent years and also as being a by product it serves as an Eco Friendly way of utilizing the product without dumping it on ground.

Keywords: GGBS, GGBS in concrete, other materials with GGBS.

I. Introduction

General:
Ground Granulated Blast furnace Slag (GGBS) [1] is a by product from the blast furnaces used to make iron. These operate at a temperature of about 1500 degrees centigrade and are fed with a carefully controlled mixture of iron ore, coke and limestone. The iron ore is reduced to iron and the remaining materials from a slag that floats on top of the iron. This slag is periodically tapped off as a molten liquid and if it is to be used for the manufacture of GGBS it has to be rapidly quenched in large volumes of water. The quenching optimises the cementitious properties and produces granules similar to coarse sand. This ‘granulated’ slag is then dried and ground to a fine powder.

Although normally designated as “GGBS” in the UK, it can also be referred to as “GGBS” or “Slag cement” Concrete is basically a mix of fine aggregate, coarse aggregate and cement. The main problem is the original conventional materials are depleting and we are in hunt for alternate building materials which lands us here on the purpose of GGBS. Being a by product and waste using it effectively up to some extent serves as a step for a greener environment and at the same time keeping in mind that the strength of the concrete doesn’t degrade by the usage GGBS.

Fig 1: Sources of Ground Granulated Blast Slag
Effectively concentrating on both the factors have been successful up to a good extent and that’s what we CIVIL ENGINEERS are very keen about in the present era of construction.

II. Chemical Composition Of GGBS

The chemical composition of a slag varies considerably depending on the composition of the raw materials in the iron production process. Silicate and aluminate impurities from the ore and coke are combined in the blast furnace with a flux which lowers the viscosity of the slag. In the case of pig iron production the flux consists mostly of a mixture of limestone and forsterite or in some cases dolomite. In the blast furnace the slag floats on top of the iron and is decanted for separation.

Typical chemical composition:
- Calcium oxide = 40%
- Silica = 35%
- Alumina = 13%
- Magnesia = 8%

The glass content of slag’s suitable for blending with Portland cement typically varies between 90-100% and depends on the cooling method and the temperature at which cooling is initiated. The glass structure of the quenched glass largely depends on the proportions of network-forming elements such as si and Al over network-modifiers such as Ca, Mg and to a lesser extent Al. Increased amounts of network-modifiers lead to higher degrees of network DE polymerization and reactivity. It is a granular product with very limited crystal formation, is highly cementitious in nature and, ground to cement fineness, and hydrates like Portland cement.

Typical physical properties:-
- Colour : off white
- Specific gravity : 2.9
- Bulk density : 1200 Kg/m³
- Fineness: 350 m²/kg

III. Applications And Uses Of GGBS

GGBS is used to make durable concrete structures in combination with ordinary Portland cement and/or other pozzolanic materials. GGBS has been widely used in Europe, and increasingly in the United States and in Asia (particularly in Japan and Singapore) for its superiority in concrete durability, extending the lifespan of buildings from fifty years to a hundred years.

Two major uses of GGBS [2] are in the production of quality-improved slag cement, namely Portland Blast furnace cement (PBFC) and high-slag blast-furnace cement (HSBFC), with GGBS content ranging typically from 30 to 70% and in the production of ready-mixed or site-batched durable concrete.

Concrete made with GGBS cement sets more slowly than concrete made with ordinary Portland cement, depending on the amount of GGBS in the cementitious material, but also continues to gain strength over a longer period in production conditions. This results in lower heat of hydration and lower temperature rises, and makes avoiding cold joints easier, but may also affect construction schedules where quick setting is required.

Uses Of GGBS

The major use of GGBS is in ready mixed concrete, and it is utilised in a third of all UK [2] ‘ready-mix’ deliveries. Specifiers are well aware of the technical benefits, which GGBS imparts to concrete, including:
- Better workability, making placing and compaction easier.
- Lower early age temperature rise, reducing the risk of thermal cracking in large pours.
- Elimination of the risk of damaging internal reactions such as ASR
- High resistance to chloride ingress, reducing the risk of reinforcement corrosion
- High resistance to attack by sulphate and other chemicals
- Considerable sustainability benefits.

In the production of ready mixed concrete, GGBS replaces a substantial portion of the normal Portland cement concrete, generally about 50 %, but sometimes up to 70%. The higher the portion, the better is the durability. The disadvantage of the higher replacement level is that early age strength development is somewhat slower. GGBS is also used in other forms of concrete, including site-batched and precast. Unfortunately, it is not available for smaller-scale concrete production because it can only be economically supplied in bulk. GGBS is not only used in concrete and other applications include the in-situ stabilisation of soil.
GGBS is used as a direct replacement for Portland cement, on a one-to-one basis by weight. Replacement levels for GGBS vary from 30% to up to 85%. Typically 40 to 50% is used in most instances. For on the ground concrete structures with higher early-age strength requirement, the replacement ratio would usually be 20 to 30%. For underground concrete structures with average strength requirement, the replacement ratio would usually be 30 to 50%. For mass concrete or concrete structures with strict temperature rise requirement, the replacement ratio would usually be 50 to 65%. For the special concrete structures with higher requirement on durability i.e, corrosion resistance for marine structures, sewerage treatment plants etc,. the replacement ratio would usually be 50 to 70%.

IV. GGBS Concrete

GGBS Proportions
On its own, ground granulated blast furnace slag (GGBS) hardens very slowly and, for use in concrete, it needs to be activated by combining it with Portland cement. A typical combination is 50% GGBS with 50% Portland cement, but percentages of GGBS anywhere between 20 and 80 % are commonly used. The greater the percentage of GGBS, the greater will be the effect on concrete properties.

Setting Time
The setting time of concrete is influenced by many factors, in particular temperature and water/cement ratio. With GGBS, the setting time will be extended slightly, perhaps by about 30 minutes. The effect will be more pronounced at high levels of GGBS and/or low temperatures. An extended setting time is advantageous in that the concrete will remain workable longer and there will be less risk of cold joints. This is particularly useful in warm weather.

Water Demand
The differences in rheological behaviour between GGBS and Portland cement may enable a small reduction in water content to achieve equivalent consistence class.

Consistency (SLUMP)
While concretes containing GGBS have a similar, or slightly improved consistence to equivalent Portland cement concrete, fresh concrete containing GGBS tends to require less energy for movement. This makes it easier to place and compact, especially when pumping or using mechanical vibration. In addition, it will retain its workability for longer.
Early Age Temperature Rise

The reduction involved in the setting and hardening of concrete generates significant heat and can produce large temperature rises, particularly in thick section pours. This can result in thermal cracking. Replacing Portland cement with GGBS reduces the temperature rise and helps to avoid early age thermal cracking. The greater the percentage of GGBS, the lower will be the rate at which heat is developed and the smaller the maximum temperature rise.

Strength Gain In GGBS Concrete

With the same content of cementitious material (the total weight of Portland cement plus GGBS), similar 28 day strengths to Portland cement will normally be achieved when using up to 50% GGBS. At higher GGBS percentages the cementitious content may need to be increased to achieve equivalent 28 day strength. GGBS concrete gains strength more steadily than equivalent concrete made with Portland cement. For the same 28 day strength, a GGBS concrete will have lower strength at early ages but its long term strength will be greater, the reduction in early strength will be most noticeable at high GGBS levels and low temperatures. Typically a Portland cement concrete will achieve about 75 percent of its 28 day strength at seven days, with a small increase of five to ten percent between 28 and 90 days.

By comparison, a 50% GGBS concrete will typically achieve about 45 to 55% of its 28 day strength at seven days, with a gain of between 10 and 20% from 28 to 90 days. At 70% GGBS, the seven day strength would be typically around 40 to 50% of the 28 day strength, with a continued strength gain of 15 to 30% from 28 to 90 days. Under normal circumstances, the striking times for concretes containing up to 50% GGBS, do not increase sufficiently to significantly affect the construction programme. However, concretes with higher levels of GGBS will not always achieve sufficient strength after one day to allow removal of vertical formwork, particularly at lower temperatures, lower cementitious contents and in thinner sections.
Ground granulated blast furnace slag (GGBS) is off-white in colour and substantially lighter than Portland cement. This whiter colour is also seen in concrete made with GGBS, especially at addition rates of 50% and above. The more aesthetically pleasing appearance of GGBS concrete can help soften the visual impact of large structures such as bridges and retaining walls. For coloured concrete, the pigment requirements are often reduced with GGBS and the colours are brighter.

**Sustainability**

Ground granulated blast furnace slag ‘GGBS’ is one of the ‘greenest’ of construction materials. Its only raw material is a very specific slag that is a by-product from the blast furnaces manufacturing iron. Manufacturing of ‘GGBS’ utilises all of the slag and produces no significant waste. As well as the environmental benefit of utilising a by-product, ‘GGBS’ replaces something that is produce by a highly energy intensive process. By comparison with Portland cement, manufacture of GGBS requires less than a fifth the energy and produces less than a fifteenth of the carbon dioxide emissions. Further ‘green’ benefits are that manufacture of GGBS does not require the quarrying of virgin materials, and if the slag was not used as cement it might have to be disposed of to tip.

Each year, the UK uses up to two million tonnes of GGBS as cement, which:

- Reduces carbon dioxide emissions by some two million tonnes
- Reduces primary energy use by two thousand million Kwh
- Saves three million tonnes of quarrying
- Saves a potential landfill of two million tonnes

In 2010, the average emission by the membership of the CSMA to produce 1 tonne of GGBS was 67 kg CO2e. The apparent increase over the figure reported for 2007 is due to a widening of the boundaries and to the use of different conversion factors; the CO2e emissions for GGBS have not changed significantly since 2007.

**Micro Structure**

Concrete containing ground granulated blast furnace slag (GGBS) is less permeable and chemically more stable than normal concrete. This enhances its resistance to many forms of deleterious attack, in particular:

- Disintegration due to sulphate attack
- Chloride related corrosion of reinforcement
- Cracking caused by alkali silica reaction
Permeability And Chemical Stability

The reaction between GGBS, Portland cement and water are complex. When Portland cement reacts with water, the insoluble hydration products (mainly calcium silica hydrates) form close to the cement particle. The more soluble product of hydration (Calcium hydroxide) migrates through the pore solution and precipitates as discrete crystals, surrounded by large pores. When GGBS particles are also present, both the GGBS and Portland cement hydrate to form calcium silicate hydrates.

Additionally, the GGBS react with the excess of calcium hydroxide to form a finely dispersed gel, which fills the larger pores. The result is a hardened cement paste, which contains far fewer calcium hydroxide crystals and therefore has fewer large capillary pores. The reduction in free calcium hydroxide makes concrete chemically more stable, and the finer pore structure limits the ability of aggressive chemicals to diffuse through the concrete.

Corrosion Of Reinforcement By Chloride

Steel embedded in concrete is normally protected against corrosion by the alkalinity created inside concrete by hydrated cement. In such conditions, a passive layer forms on the surface of the steel and rusting is inhibited. However, if significant amounts of chloride are able to penetrate the concrete this protection can be destroyed and the embedded steel will rust and corrode. Because of its finer pore structure, GGBS concrete is substantially more resistant to chloride diffusion than Portland cement concrete. For reinforced concrete structures exposed to chlorides, the use of GGBS will give enhanced durability and a longer useful life. This applies in many situations, including highway structures (particularly bridge parapets), car parks subjected to de-icing salts and coastal environments. Generally the higher the proportion of GGBS, the greater will be the resistance to chloride penetration. Typically, use of 50% GGBS will give high resistance to chloride and use of 70% GGBS will give very high resistance.

Alkali-Silica Reaction (ASR) [5]

Alkali ions (sodium and potassium) are present in Portland cement. They are readily soluble in water and are released into the pore solution of concrete when the cement hydrates. Here they can slowly react with certain types of silica in the aggregate to produce an alkali-silicate gel. In wet conditions this gel can absorb water, swell and exert sufficient pressure to crack the concrete. In some cases the resultant cracking is sufficient to endanger structural integrity. The consequences of ASR can be severe and there is no reliable cure for affected structures. Addition of appropriate percentages of GGBS is an effective means of minimising the risk of damaging ASR. Detailed recommendations are given in Building Research Establishment Digest 330:2004, “Alkali Silica Reaction in concrete”. BS8500:2006 now refers to this digest rather than including specific recommendations for ASR. With GGBS, the BRE digest requirements are normally easily satisfied. By incorporating GGBS, the BRE digest requirements to limit the reactive alkali content of the concrete are normally easily satisfied. With normal reactivity aggregates and GGBS percentages of at least 40 percent, the GGBS is deemed to make no contribution towards the reactive alkali content.

Addition To Concrete

In the UK [5], GGBS is normally supplied as a separate material and added at the concrete mixer. However, it can also be blended with Portland cement in a cement factory and marked as ‘Portland slag’ or ‘Blast furnace’ cement. The British Standard for Concrete [7] [BS 8500] allows either approach to be used. These alternative routes have little effect on the properties of the finished concrete and the savings in carbon dioxide emissions are broadly similar. Generally, adding the GGBS at the concrete mixer:

- Reduces transport burdens, because the addition can be delivered directly to the concrete plant without having to go via a cement factory.
- Provides more accurate proportions, because the materials are weigh-batched in a concrete plant.

A major advantage of adding GGBS[5] at the concrete mixer, rather than at the cement factory, is the flexibility to vary the proportion and thereby optimise the technical performance of the concrete. The most widely used GGBS proportion is 50% but it is advantageous to be able to vary the proportion to meet specific requirements, e.g.

- 66 to 80% GGBS may be best for high sulphate resistance or for high resistance to chloride ingress.
- 50 to 70% GGBS may be best to reduce heat of hydration and control early-age cracking.
- 25 to 40% GGBS may be best to avoid extended finishing times for applications such as power-floated floors.
- 20 to 40% GGBS may be best to ensure high early strength.
- 80 to 95% GGBS may be best to achieve very low early-strength gain in applications such as secant piles.
- 30 to 45% GGBS may be best to avoid excessive retardation in cold weather.
Soil Stabilisation
Stabilisation of soil with cementitious binders is widely used in road, pavement and foundation construction, to improve the engineering properties of the soil, by:
✓ Increasing the strength and bearing capacity.
✓ Controlling the volume stability against swell-shrink caused by moisture changes.
✓ Increasing the resistance to erosion, weathering and traffic loading.

Stabilisation of the existing soil will normally be a much more sustainable solution than importing aggregate. Use of a lime + ggbs combination offers significant advantages for soil stabilisation. The major advantage is in inhibiting the deleterious swelling that can occur with clays containing sulphates.

Health & Safety
GGBS is a fine powder that may cause mechanical irritation to the eyes and respiratory system, if appropriate dust control measures are not implemented [7]. Manufacturers and suppliers of GGBS provide Safety information Sheets to enable appropriate risk management measures to be identified and applied.

VI. Conclusion
The movement of moisture of GGBS mixes, probably due to the dense and strong microstructure of the interfacial aggregate/binder transition zone are probably responsible for the high resistance of GGBS mixes to attack in aggressive environments such as silage pits. The mineral composition of GGBS cement paste (with less aluminates and portlandite than Portland cement) probably contributes to this resistance.
As we have seen GGBS is a good replacement to cement in some cases and serves effectively but it can’t replace cement completely. But even though it replaces partially it gives very good results and a greener approach in construction and sustainable development which we are engineers are keen about today.
