Abstract: Metal matrix composite (MMC) material is one which contains two or more materials with different physical and chemical properties with two constituent parts, one being a metal and other may be metal, ceramic or fiber. Due to their light in weight, high strength and high hardness, among various MMC’s, aluminium MMC is the most widely used. The wide range of availability of aluminium has made it an important material for manufacturing many components. An aluminium alloy which has low tensile strength and hardness is been composited with other materials to improve its properties and reduce its drawbacks. aluminium is been composited with silicon carbide that drastically increases the properties. In this study we developed aluminium metal matrix hybrid composite by reinforced Aluminium 8090 alloy with silicon carbide (SiC) by method of stir casting. Maintaining a Constant amount of aluminium and silicon carbide is varied to obtain a two different compositions of (AlSi) composites. The mechanical properties such tensile strength hardness are studied. The composites are tested for their flexural and impact properties and the result shows that all the properties of hybrid composite are superior than base metal.

Keywords: Metal matrix composite, Aluminium alloy 8090, silicon carbide (sic), Stir casting process.

1. Introduction

A composite material is a combination of two or more chemically distinct materials to form a stronger material. The term “composite” broadly refers to a material system which is composed of a discrete constituent (the reinforcement) distributed in a continuous phase (the matrix), and which derives its distinguishing characteristics from the properties of its constituents, from the geometry and architecture of the constituents, and from the properties of the boundaries (interfaces) between different constituents. Composite materials are usually classified on the basis of the physical or chemical nature of the matrix phase, e.g., polymer matrix, metal-matrix and ceramic composites MMC (Metal matrix composites) are metals reinforced with other metal, ceramic or organic compounds.

Reinforcements are usually done to improve the properties of the base metal like strength, stiffness, conductivity, wear and corrosive resistance etc. Aluminium, Silicon, Copper, Titanium, Magnesium, and Nickel metals are widely used for preparation of metal matrix in composites materials. In Metal Matrix Composites (MMCs), aluminium and its alloys have attracted most attention as base metal in metal matrix composites because of its low density, low weight, high strength, superior malleability, high machining, excellent corrosion resistance and good their mal and electrical conductivity, etc. In recent years, Al based composite materials have gained significance in aerospace, automotive and structural applications due to their enhanced mechanical properties and good stability at high temperature. The various reinforcements used are Silicon Carbide, Aluminium Oxide, Titanium carbide, Boron Carbide, etc.

SiC reinforcement increases the tensile strength, hardness, density and wear resistance of Al and its alloy. The interfacial reaction between the materials is also important because if the load carrying transferred to the interface, it will affect the mechanical properties of the composite material. The way of reinforcement also changes the physical properties like wear resistance, hardness, thermal conductivity. The reinforcement can be either continuous or discontinuous. The MMC’s prepared by discontinuous process are isotropic and by continuous process are anisotropic structure. The anisotropic structure occurs because the fibers such as carbon fibers and monofilament wires embedded in to the matrix in particular direction. For processing of AMMCs at industrial scale, the processing operations classified in to two main groups. Liquid state processes and solid state processes. Stir casting, compo casting and squeeze casting spray casting and in situ (reactive) processing; ultrasonic assisted casting comes under the liquid state process. For discontinuous metal matrix composites various techniques are available. Among them stir casting method is generally preferred. Its advantages lie in its simplicity, flexibility and applicability to large quantity of production. It is also attractive because of minimized final cost of the product. It also allows very large sized components to be fabricated. In the stir casting method,
there are several factors that need considerable attention, including the difficulty of achieving a uniform
distribution of the reinforcement. The composites, before fabrication process, are heat treated to an under aged
condition as the materials can be shaped more easily and after fabrication, these materials are heat treated to the
peak aged condition so as to provide improved mechanical properties.

II. Experimental Details

A. Material

In this work, matrix material is aluminum while Silicon carbide in powder form are reinforced with the
varying volume fractions as reinforcement. Silicon Carbide is one of the widely used ceramic particles due to its
properties like high hardness and low coefficient of thermal expansion ($4.6 \times 10^{-6} \, ^\circ C$). It is used in automotive
brakes and clutches. The properties of the matrix and the reinforcements are shown in table 1

B. Stir casting process

Stir casting process is used to fabricate composite consists of an induction furnace with three mild steel
stirrer blades. Here, the reinforcements are distributed into molten aluminium matrix by mechanical stirring.
During preheating stage, the reinforcements are heated separately nearer to main process temperature of 400°C
while aluminium is melted in a separate crucible at a temperature of 830°C. Now, the preheated reinforcements
are mechanically mixed with the molten aluminium below their melting temperature. Then, the mixture is
poured into the die and allowed to solidify. The weight percentage of the matrix and the reinforcements for
different samples are shown in table 2.

V. Conclusions

The above review for the aluminum based metal matrix composite leads to the following conclusions:

1. Finally, We have concluded that the composition of Al (93%) + SIC (7%) is having more efficient yield and tensile strength, hardness then the composition of Al (97%) + SIC (3%). So that this composite material can use in cam shaft for more efficiency and life period.

2. Stir casting process is well suited and economical for the preparation of AMMC’s with desired properties.

3. By increasing the wt % and decreasing the particle size of reinforced material in the aluminium composites the hardness, tensile strength increases.
