Abstract: Nanofluid, a simple product of nanotechnology has become a topic of attraction due to its extraordinary heat transfer performance in various areas including cooling, power generation, defense, nuclear, space, microelectronics and biomedical appliances. However, preparation and stabilization of such fluids are indeed a matter of concern for better understanding. For the last decade numerous research and development works have been done in the synthesis and stability of such materials. In this contribution, a brief review has been presented to provide an update about the preparation and stabilization methods of nanofluids.

Keywords: Nanofluids, preparation, stability

I. Introduction

Nanofluids are colloidal suspension of ultra-fine metallic or nonmetallic particles in a given fluids. Despite all other properties, it is well known for its high thermal conductivity and better response as heat transfer medium. Nanofluids can be of two kinds such as metallic nanofluids and nonmetallic nanofluids. Metallic nanofluids are prepared by dispersing nanoparticle made from metals such as aluminum, copper, nickel etc. and nonmetallic nanofluids are made by dispersing nanoparticles of nonmetals i.e. metal oxides, various allotropes of carbon (Graphene, CNT) etc. Synthesis and stability of nanofluids are the two very primary requirements to study nanofluids. The proper utilization of the potential of nanofluids depends on the preparation and stability of nanofluids. The later part of this section is intended to present these two very important terms.

1.1. History and development of nanofluids

The twenty first century is an era of technological development and has already seen many changes in almost every industry. The introduction of nanoscience and technology is based on the famous phrase “There’s Plenty of Room at the bottom” by the Nobel Prize winning physicist Richard Feynman in 1959. Feynman proposed the concept of micromachines. In 1974 Scientist Norio Taniguchi first used the term ‘Nanotechnology’. After that in 1995, scientist Choi of Argonne Laboratory (USA) successfully prepared nanofluid. After the establishment of such a landmark in the history of nanoscience, nanofluids grab the attention of the most of the researchers around the globe. In recent years the craze about nanofluid research has gone to such a hype that in the year 2011 alone, there were nearly700 research papers where the term nanofluid was used showing abreakneck growth from 2006(175) and 2001(10)[1]. Figure1 shows an exponential growth in nanofluid research.

1.2. Potential features of nanofluids

Nanofluids have some uncommon features those make them very special for various engineering applications. Some of the special qualities of nanofluids are:

I. Rise in thermal conductivity beyond exception and much higher than theoretical predictions.
II. Ultrafast heat transfer ability.
Better stability than other colloids.  
Better lubrication.  
Reduction of friction coefficient.  
Reduction in pumping power.  
Reduction of erosion and clogging in micro channels.  
Better stability.

## II. Preparation of nanofluids

Preparation of nanofluids is the first foot-step to the experimental studies of nanofluids. There are two primary methods to prepare nanofluids: the single-step preparation process and the two-step preparation process. A brief discussion on nanofluid preparation processes is given in 2.1, 2.2 and 2.3.

### 2.1. Single-step preparation process

The single-step preparation process indicates the synthesis of nanofluids in one-step. Several single-step methods have been arrived for nanofluid preparation. Akoh et al. [2] developed a single-step direct evaporation method. This process is familiar as VEROS (Vacuum Evaporation onto a Running Oil Substrate). But it was difficult to separate nanoparticles form fluids. Eastman et al. [3] developed a modified VEROS technique, in which Cu vapor is directly condensed into nanoparticles by contact with flowing low-vapor-pressure ethylene glycol. Zhu et al. [4] presented a single-step chemical process for the preparation of Cu nanofluids by reducing CuSO$_4$.5H$_2$O with NaH$_2$PO$_4$.H$_2$O in ethylene glycol under microwave irradiation. This method also proved to be a good way to produce mineral oil based silver nanofluids. Lo et al. [5] developed vacuum based submerged arc nanoparticle synthesis to prepare CuO, Cu$_2$O and Cu based nanofluids with different dielectric liquids. A suitable power source is required to produce an electric arc between 6000-12000°C which melts and vaporizes a metal rod in the region where arc is created. The vaporized metal is condensed and then dispersed by deionized water to produce nanofluids. An advantage of one-step synthesis method is that nanoparticle agglomeration is minimized. But primeproblem is that only low vapor pressure fluids are compatible with such a process. One-step preparation process (chemical process) of nanofluids is given in the Figure2.

![Figure2: One-step preparation process of nanofluids](image)

### 2.2. Two-step preparation process

Two-step preparation process is extensively usedin the synthesis of nanofluids by mixing base fluids with commercially available nanopowders obtained from different mechanical, physical and chemical routes such as milling, grinding, and sol-gel and vapor phase methods. An ultrasonic vibrator or higher shear mixing device is generally used to stir nanopowders with host fluids. Frequent usageof ultrasonication or stirring is required to reduce particle agglomeration. Eastman et al. [3], Lee et al. [6], Wang et al. [7] used two-step method to produce alumina nanofluids. Murshed et al. [8] prepared TiO$_2$-water nanosuspension by the same method. Xuan et al. [9] used commercially available Cu nanoparticles to prepare nanofluids of both water and transformer oil. Kim et al. [10] used two-step method to prepare CuO dispersed ethylene glycol nanofluids by Sonication and without stabilizers. Two-step method can also be used for synthesis of carbon nanotube based nanofluids. Single-walled and multi-walled carbon nanotubes are first produced by pyrolysis method and then suspended in base fluids with or without the use of surfactants [30, 40, 41]. Some authors suggested that two-step process is very suitable to prepare nanofluids containing oxide nanoparticles than those containing metallic nanoparticles [11]. Stability is a big issue that inherently related to this operation as the powders easily aggregate due to strong van der Walls force among nanoparticles. In spite of such disadvantages this process is still popular as the most economic process for nanofluids production. The most common two-step method is shown in Figure3.
2.3. Other methods

There are some other literatures where different approaches (other than these two procedures) were expressed. Feng et al. [12] used aqueous organic phase transfer method for preparation of gold, silver, platinum nanoparticles. Phase transfer method can also be applied to prepare kerosene based Fe$_3$O$_4$ nanofluids which do not show time dependent thermal conductivity. Grafting of oleic acid onto the surface Fe$_3$O$_4$ makes it compatible with kerosene [13].Wei et al. [14] established a continuous flow microfluidic microreactor to synthesize copper nanofluids. The microstructure and properties of nanofluids can appropriately be varied by adjusting parameters such as concentration, flow rate, additives. Moreover a novel preparation of aqueous CuO nanofluid can be done through novel precursor transformation method with the help of ultrasonic and microwave irradiation [15]. Here the precursor, Cu (OH)$_2$ is completely converted to CuO in water under that process. The use of ammonium citrate is to prevent the growth and aggregation of nanoparticles, resulting in a stable CuO aqueous nanofluid with higher thermal conductivity than those prepared by other dispersion methods.

III. Stability of nanofluids

Nanofluids which can lose their potential to transfer heat due to their proneness to coagulation. Therefore, investigation on stability is an unavoidable issue that can alter the thermo-physical properties of nanofluids for application and also important to analyze the influential factors to the stability of such suspensions. This section contains the stability evolution methods and stability enhancement processes along with a detail about the stability mechanisms related to nanofluids.

3.1. Stability evaluation methods for nanofluids

3.1.1. Zeta potential analysis

Zeta potential is the potential difference between the dispersion medium and the stationary layer of fluid attached to the particle. The zeta potential indicates the degree of repulsion between adjacent, similarly charged particles in dispersion (Figure4). So, colloids with high zeta potential (negative or positive) are electrically stabilized while colloids with low zeta potentials tend to coagulate or flocculate. Nanofluids with zeta potential from 40-60 mV are believed to have excellent stability. A lot of researchers have gone through zeta potential test of nanofluids. Kim et al. [16] used zeta potential analysis for Au nanofluids and found out outstanding stability. Zhu et al. [17] measured the zeta potential of Alumina-water based nanofluids under different pH values and different SDBS concentrations. The DLVO theory was applied to measure the attractive and repulsive potentials.

3.1.2. Sedimentation method

Sedimentation method is the most elementary method for evaluation of nanofluids [14]. An external force field is applied to start the sedimentation of nanoparticles in the nanofluids. The weight of sediment or the volume of sediment indicates the stability of nanofluids. Nanofluids are generally considered to be stable if the concentration of the supernatant particles remains constant with time. Zhu et al. [18] used the principle of
sedimentation method in his own experimental setup to measure the stability of graphite suspension. Use of camera has proven to be a suitable aid to capture sedimentation photographs for observing the stability of nanofluids [36]. Waiting time for capturing photos links up with quality of nanofluids during preparation and well use of applied methods to make astable nanofluids. Wei et al. captured photographs of their samples within 24 hours after preparation. Wang et al. followed the path for testing sedimentation of alumina-water nanofluid [32].

3.1.3. Centrifugation method

Sedimentation method is very time consuming as it requires a long period of observation. So centrifugation method is developed for stability evaluation. Sing et al. [19] used centrifugation method to evaluate the stability of silver nanofluid prepared by reducing AgNO₃ and selecting PVP as the stabilizer. An excellent stability of silver nanofluids was found due to the protective role of PVP because it decelerates the agglomeration of particles by steric effect.

3.1.4. Spectral analysis method

Spectral analysis via UV-vis spectrophotometer is another useful way to evaluate stability of nanofluids. The advantage over other methods that UV-vis spectroscopy gives quantitative results corresponding to concentration of nanofluids. Hwang et al. [20] analyzed the stability of MWNT nanofluids by measuring the UV-vis absorption of MWNT at different sediment time.

The above three methods can be used all together to complete the stability evaluation process. For example Li et al. [21] performed zeta potential analysis, absorbency and sedimentation photography for copper nanofluids under different pH values, different dispersion types and different concentrations.

3.1.5.3 Method

In this method, stability of suspensions can be evaluated considering thermal conductivity growth caused by the nanoparticle sedimentation in a wide nanoparticle volume fraction range [34]. A new literature has found using this method to check the stability of nanofluids [35].

3.1.6. Electron microscopy and light scattering methods

Measurement of particle size distribution by microscopy and light scattering techniques are two general methods for observing particle aggregation. Very high resolution microscope such as TEM and SEM are applied to capture the digital image of nanoparticles, known as electron micrograph. Figure 5 (a, b) shows TEM and SEM photographs of CuO nanoparticles respectively [38, 39]. Cryogenic electron microscopy can be used for the same purpose if the microstructure of nanofluids is not changed during cryoation [37]. Light scattering technique can also be used for the study of complex nanosuspensions.

3.2. Stability enhancement procedures

3.2.1. Addition of surfactants

Surfactants or dispersants are generally applied to stabilize the nanofluids. Addition of surfactants lowers the surface tension of host fluids and increases the immersion of particles. Surfactants can be defined as chemical compounds added to nanoparticles in order to lower surface tension of liquids and increase immersion of particles. Several literatures talk about adding surfactant to nanoparticles to avoid fast sedimentation; however, enough surfactant should be added to particle at any particular case. In researches, several types of surfactant had been utilized for different kinds of nanofluids. Some important surfactants are: Sodium dodecyl sulfate (SDS) [22], Salt and oleic acid [23], Dodecyltrimethylammonium bromide (DTAB) [24], Hexadecyltrimethylammoniumbromide (HCTAB) [13], Polyvinylpyrrolidone (PVP) [25], Gum Arabic [26]. It should be noted that this technique cannot be applicable for nanofluids working in high temperature on account of probable damage of bonding between surfactant and nanoparticle. Additionally surfactants may
hamper heat transfer produce foam when heating. Furthermore surfactants may increase the thermal resistant between the nanoparticle and the base fluids which may lead diminish the enhancement in the thermal conductivity [27].

3.2.2. Surface modification techniques
This segment presents the surfactant free method. Injection of functional nanoparticles in the base fluids can provide long term stability of nanofluids. There are a number of examples of such modification techniques. As for example, Yang et al. [28] grafted silanes directly to the surface of silica nanoparticles in the original nanoparticle solutions. A special feature of those nanofluids was no deposition layer formed on the heated surface after a pool boiling process. The stability of carbon nanotubes can be increased by introducing hydroxyl groups onto the surface of CNTs [29]. Plasma treatment can be applied to modify the surface of diamond nanoparticles for improving their dispersion property in water [30]. Details of surface modification techniques can be found in the reference [27].

3.2.3. pH control of nanofluids
Stability of nanofluid is directly related to its electro-kinetic properties; therefore, pH control of them can increase stability due to strong repulsive forces. As for example, simple acid treatment could cause nice stability of CNT in water [31]. Lee et al. [32] investigated various pH values for Al2O3 nanofluid and observed decrease or increment of agglomeration by changing pH. Finally, it should be noted that optimized pH value is different from one sample to another. For instance, suitable pH value for alumina, copper and graphite dispersed in water are around 8, 9.5 and 2, respectively [30].

3.2.4. Ultrasonic agitation:
After preparation of nanofluids, agglomeration might occur over the time which results in fast sedimentation of nanoparticles due to enhancement of downward body force. Manson et al. [33] investigated two different nanofluids; carbon black-water and silver-silicon oil and they utilized high energy of cavitation for breaking clusters among particles.

IV. Stability Mechanisms
Stability which is the most crucial issue can be hampered by particle aggregation. Aggregation of nanoparticles is due to the sum of attractive and repulsive forces between particles. If attractive forces prevail over repulsive one then particle aggregate in clusters. Therefore enhancement of repulsive forces over attractive forces can prevent particle aggregation and ensure stability. Enhancement can be done by two mechanisms: electrostatic stabilization and steric stabilization. Here these two mechanisms are discussed in brief.

4.1. Electrostatic stabilization
Existence of an electric charge on the surfaces of particles is a major source of kinetic stability. Electrostatic stabilization occurs by adsorption of ions to the electrophilic metal surface (Figure 6). Adsorption creates an electrical double/multi-layer which results in a Columbic repulsion force between the nanoclusters. Electrostatic stabilization is a pH sensitive method and of limited use.

![Figure6: Electrostatically stable nanoparticle](image)

4.2. Steric stabilization
Steric stabilization of nanoparticles is achieved by attaching (grafting or chemisorption) macromolecules such as polymers or surfactants to the surfaces of the particles (Figure 7). The stabilization is due to the large adsorbents which provide steric barrier to prevent particles coming close to each other. For example, stability of graphite nanofluids is due the protective role of PVP as it prevents the agglomeration of nanoparticles due to steric effect [18].

![Figure7: Sterically stabilized nanoparticle](image)
V. Conclusion and Remarks:

In this review article an attempt has made to cover all the important investigations performed on the preparation and stability of nanofluids. We have come to know that two-step preparation method is accepted by the major portion of researchers as it is simple and economic. Further, we have found the steps involved in the stabilization process of these fluids. Additionally, mechanisms corresponding to stability of such fluids are also discussed. Although there are some positive outcomes of nanofluid, but the following issues should receive greater attention for their proper utilization.

- Fault free economic production technique is the most important thing for the commercialization of nanofluids.
- The shape of nanoparticles is very important for their properties; therefore a new preparation method with controllable microstructure will be an interesting research topic.
- Long term of stability and stability after a long working cycle should paid intense attention for both research and real life application.
- Development of suitable surfactants for better stability of nanofluids may be a topic of interest.
