### **Abstract:**

*A case of a 16 years old boy, who presented with multiple episodes of vomiting, sore throat and difficulty in swallowing. Within 2 days of initial presentation he was comatose and following was intubated. His SARS-CoV 2 IgG antibody report came positive and CSF analysis showed albumin-cytological dissociation. The patient recovered with intravenous methylprednisolone and intravenous immunoglobulin therapy, which was given for 5 days. Non-specific GI symptoms could be an initial symptom of post covid encephalitis and these patients may require immunosuppressive therapy.*
